3052. Multiband coaxial collinear array

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-18 09:35:30 UTC
From: Hans Peter Winkler <h.winkler@genescan.com>
Message-ID: <a9m3sh$4cvsk$1@ID-125322.news.dfncis.de>
Source record: 44694

Is it possible to build a multiband coaxial collinear array? (E.g. 80, 170 and 440 MHz) I searched with GOOGLE, at the US Patent-Server and in the Rothammel(very good german antenna-book, but I could find nothing. I would be glad about every advice or idea. Please excuse my bad english (I'm a german "Krautfresser")!

Thanks in advance
Hans Peter

3053. Help with JWMiller guide

I'm looking for a J W Miller guide and cross reference. In all my moves,
I've lost the one I had.
The one I'm looking for is beige or tan in color, was printed in the 70's (I
believe, my memory isn't
what it used to be :-)
I would gladly pay copy and shipping cost, or if you have one for sale, let
me know.

Thanks in advance!
Mark

Your low pass filter may be too close to the operating frequency and
causing angle modulation
of the signal?

Hi all,

what are the criteria for selecting one of these MOSFETs for using it in an
amplifier for HF ? Capacitance parameters Ciss, Coss and Crss only ?
Other parameters are interesting for switching applications only?

I have an amplifier(working on 40..10mtrs 100Watts pwr out) with defective
MOSFETs (2 parallel and push-pull= 4 MOSFETs)TO-220 package but identification
of the MOSFETs removed. So I tried IRF530 (high Ciss abt 920p) and could get out
about 100 Watts on 40mtrs(4Watts input pwr) but decreasing to 20Watts on 28MHz.
With the original types you could easily get out 100Watts up to 28MHz
with 0.5Watts of input power.

Any suggestions ?

This coming Sunday....

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday April 21st 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all

sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

3059. Re: AM Modulation Distortion

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-18 18:19:59 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <dh2ubu0bh7vu87kmin0fb00kfnnvqvb97o@4ax.com>
Source record: 44601

Thanks to all. Good suggestions one and all.

Following up on the AM-to-PM theory, I measured the phase shift between the square wave VCO output and the LPF sine output for varying Vdd voltages this morning. I used a Tek TDS-430 scope with automatic phase difference measurements, with channel 1 on the synthesizer VCO output and channel 2 on the 50 ohm termination at the LPF output.

With no modulation input, I adjusted my quiescent drive pot to vary the Vdd over the range of about 0.5 volts to 10.5 volts.

What I found was a close to linear phase versus voltage shift (R=0.993 for a linear fit) when I plotted 11 phase versus Vdd measurements. The conversion ratio is 2.0 degrees/volt, based upon a linear fit to the data.

I took the data at a carrier frequency a bit below the 3 dB LPF point (data at 1 MHz; 3 dB filter point ~ 1.2 MHz), so I'll take some more data well below the LPF cutoff and see if that's the problem.

My back of the envelope calculations show that for a 10 KHz sine wave modulating signal, and kp=2.0 degrees/volt (0.035 radians/volt), I have a maximum instantaneous frequency shift of 1.75 KHz.

So, it looks like AM-to-PM problem. The next step is to determine where it is occurring. And, then, how to reduce it.

3060. Re: Multiband coaxial collinear array

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-18 19:26:29 UTC
From: k7itm@aol.com
Message-ID: <3200347.0204181126.28d0116b@posting.google.com>
Source record: 44602

(Seems like a better question for the "antennas" group...)

A key problem, as I see it, is that the coaxial construction relies on each section of the coax to give you 180 degree phase shift (or equivalently 180+n*360 degrees) at the operating frequency. With lossless (and to a good approximation with low loss) line, this is achieved independent of the load impedance at each feed node along the antenna. But clearly, it occurs only for frequencies f, 3f, 5f, ..., assuming the velocity factor is constant with frequency. If you have to start adding other components to get the phase shifts you want on all operating frequencies, I think the beauty of the design is no longer there. To me, that means operation of a single structure on, say, 147MHz + 441MHz (+/- a bit on each band) makes some sense, but probably not on 80+170+440.

Cheers,
Tom

Forgot to say, calculation based on quiescent point of 5.5 volts, AM
modulation 10 V PP (corresponding to Vdd swing from 0.5 volts to 10.5
volts on modulation peaks).

Source record: 44605

Hi! My name is Bruno from Genoa North Italy.(IK1VHX callsign)
I'm looking for very good project about HF preselector tunable from 1.8 MHz
to 30 MHz passive or active with not high gain preamplifier (10 or 20 dB max
AGC controlled) low noise and high IMD.
Do you have any schematic diagram full solid state or with tubes?
I'd like to homebrew a professional receiver from 1.8 to 30 MHz all modes
demodulator high level first mixer and ten band pass filters automatic
selected from DDS used to drive first OL.
I'd like to use a tunable preselector after band pass filters to improve
performance of receiver and cut out indesired signals.
Thanks and 73 de IK1VHX bruno

Please excuse the cross-posting, I'm really not sure where's
the best place to ask.
I'm looking for data - pin out, max ratings, typical
operating conditions - for these old tube types:

CV25 (also called 4242C or VT4C)
CV266 (809)
CV622 (802)
CV704 (RK20-A, 5B-600A)

I've tried web and newsgroup searches without success.
Email me direct if you like, or if this is off topic for
this group.

Thanks a mil

Dave McDonald

I don't have the specs to hand but can help further with equivalents
from my old "Service Valve & Semiconductor Equivalents" book
(published by RSGB in 1967).
CV25 : ES85 (AEI), 424A (STC), 242C (Am), UE311 (Am), 211 (Am)
CV622 : 802 (Am)
CV704: RK20A (Am), CV624
Now for CV624 we have : 804 (Am).

Where Am must be American Manufacture (these days we'd say "USA").
and, of course "valve" = tube.

Chris Muriel, G3ZDM, Manchester, UK

"AB Brown" <abbrown@nospammail.com> wrote in message news:a93aas$68n$1@slb1.atl.mindspring.net...
Currently, I am using two amateur radios for communicating: one is the Icom 718 and the other, strictly for 10 meters, is an older Realistic HTX-100. I have used the HTX-100 for about 5 years now and I just obtained the Icom less than 6 months ago. I am puzzled by something though that I was wondering if anyone could address- the noise blanker on the HTX is FAR superior to the one on the Icom. I am wondering why? The Icom was a lot more expensive and I just figured it would have a better blanker. It has AF DSP option, which I tried, and was disappointed. In every case on 10 meters, the HTX receives better due to blanked noise effectiveness.

I doubt I could internally modify the Icom's blanker for better performance so I am wondering if I could add an external, synchronous (or other ?) type noise blanker at the antenna input. I have read a few things about this type of blanker and, apparently by using noise generators, you can match the phase of incoming noise and cancel it out. Any suggestions for a blanker, either internal or external? I understand the synchronous type is better at lower Mhz, but will it work for 10/15 meters?

I believe the main sources of noise at my QTH are computer (of course) and pole transformer noise. The computer noise is easily solved (by turning off my monitor) but I have experienced the transformer noise for many years, and the HTX blanker always nullified it.

Appreciate any suggestions from the groups.

Thanks,
AB

No problem.. This is the proper use of cross posting. One
should use crossposting to a few closely reverent newsgroups
rather than sending individual posts to each.

It depends on what kind you are talking about; the small Epson types, such as the SG636 around 4 dollars each in small quantities. Also, you can even buy user programmable units for not much more. eBay? Might be worth a shot.

Hello Tom,

you're right,but I didn't get an answer to my question at the "antennas" group, so I tried it (successfully!thanks!) in this group.
I think you're right with your technical answer too, unfortunately for me, because I thought such an antenna would be the best for my applications. I think I will build one for 440 MHz (from 8 halfwave-pieces of RG58 or RG213) at this weekend, hoping it brings a little performance on the other frequencies, though they're not harmonically related.

Hi there,
I can buy not for much money 2 pieces of the professional 300 watts HF solid state modules. If I buy it I would like to combine it into one PA. So I look for some transformer combiner circuit working well with that power on the frequecy range of 1.5 to 30 Mc.
Another question is a set of switched low-pass filters working with 600 watts. And a power supply 50V DC/20A...
:-)))
Can anyone help me?
Thanks,
George, SP2BRZ.

The brute force method found in my 70's era txrs is to switch off powr to
the reciever when the transmitter is keyed. When the transmitter is unkeyed,
the power to the transmitter is turned off and power to the reciever is
turned back on.
thanks, John.

Hi Bruno,

In a most cases receiver front end does not need very much of a
(takeover) gain.
Depending on the Noise Figure of your (first) mixer, the front end has
to provide just enough gain to establish required sensitivity. Any
extra gain will degrade the IM performance of the radio.
In most cases 3 to 8 dB of net gain at the front end is enough.
Tunable preselector is a very conservative and effecient tool to
minimize out of band interferers. But again, for in-band interfering
signals you want to have as little gain as possible considering that
you met your sensitivity considerations. For the tube RF amp. I would
use 1AD4 submin. tube (also known as 5678 submin. tube). This tube is
cheap and widely available. Makes a good mixer as well. This tube is a
direct cathode 1.25 Volt filament voltage and it can work with about
50 volt of plate voltage. Very safe!

In order to avoid switching "pops" most rigs use a JFET to interrupt the input signal to the amp. You can find a number of examples in the ARRL Handbook.

3088. HV capacitor question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-20 20:52:11 UTC
From: brian_mull@agilent.com
Message-ID: <59e3ae16.0204201252.668deb99@posting.google.com>
Source record: 44630

Hi all

I am trying to homebrew a high voltage air variable cap for an antenna tuner.
What is the relationship between peak voltage rating, working DC voltage, and dielectric breakdown voltage. I ask because I saw an air variable cap advertised on the RF Parts web site that had a peak rating of 5300 volts with a plate spacing of only .12 inches. This doesn't add up with the numbers I calculate using data from the ARRL handbook, so I figure I must be confused somewhere. TIA.

Most of the rating you read on air caps, are for DC, you might figure that
RF would be 60% of that rating.
Weather your system exceeds that rating, will depend on if your feed is a
voltage or current node.

That is interesting information. I really didn't know how much a
new one would cost. The used Efratom or FE ones show up on eBay
and go for a few hundred US$ or can be had from Lehman Scientific
for $500. But I do wonder what their remaining life would be.
Probably enough for anything I'd need.

3091. SIMPLE BFO

Is there such a "thing" as a "passive" bfo? i want to add an external bfo to an am shortwave receiver. The only problem is i want a "batteryless" bfo or a least one that takes a AA battery.

I don't think a rubidium standard is a good choice for most people.

IMHO, the average user is better off with a GPS-disciplined frequency standard like the one Brooks Shera described in the July '98 QST, one of the HP Z3801A GPS standards that are commonly seen on eBay, or a Trimble Thunderbolt unit (do a Google search for more info on any of these).

All of these options cost about as much as a used rubidium standard (in Shera's case, potentially quite a bit less). They all offer rubidium-class long-term stability, and for all practical purposes, perfect short-term stability as well. But unlike Rb sources, they don't use any exotic, failure-prone parts, so they can be left running 24/7 with no worries (and no aging, again unlike Rb sources).

You can count on the output of a GPS source to be substantially less than one part per billion, or better than one hertz per GHz. Sure, a rubidium source is an order of magnitude better over short periods, but few users outside of a physics laboratory need that kind of performance.

> In order to avoid switching "pops" most rigs use a JFET to interrupt
> the input signal to the amp. You can find a number of examples in the
> ARRL Handbook.

A low power approach is to switch the bypass pin to ground. You can easily do this with a switching transistor such as the 2N3904 or equivalent. I believe the standby current during mute is around 600 uA. This also stops the bias and the output DC level shouldn't jump too much and will not make a big pop. This technique was used in the design of the Motorola HT90/440. If the ic's design was changed over the years this may not work (I haven't checked the schematic of the ic lately).

Another trick is to short out the negative feedback of an op amp ahead of the mic amp used as a preamp. As you know gain = Rf/Rin and if Rf is 0, then the gain is very negative. I used this in the Motorola Saber X controller. The signal driving the NPN was the raw battery at around 12vdc and the opamp was running at 7.5vdc so when the NPN xsistor was swithced on, the amp just shutted down as far as gain was concerned. Squelch pops were negligable as the circuit was driving a pair of headphones were this performance was crucial.

If you need a scheamtic, let me know and I'll see what I can come up with.

I am not aware of any kind of passive external BFO. If you modify a section of the I.F. string to provide some regeneration when needed, you might consider that semi-passive as it does not comprise a dedicated oscillator stage. (Hi Hi).

Just build a solid state BFO circuit on a small board and mount it inside the Rcvr. You can include rectification of the filament voltage, appropriate dropping resistor and regulator to get the low voltage DC needed for the circuit.

If you don't want to add a switch to the front panel of the Rcvr, you are probably going to have some kind of wiring exiting the equipment from the rear. If that is the case, you might as well run the third wire and pull power from the Rcvr for the external BFO.

Being posted for a friend
PLEASE respond to him at link provided BELOW

Hello friends,

does anybody have a VHF ENGINEERING amplifier model BLE 10/80 420-450MHz ?

I have to repair one of this model and I'm looking for more information's.
Inside at this amplifier I have discovered a burn resistor "flying" on the
board...

Value of this is missing and also the location where was solder.
Please if you have one of this can you help me ?

thank you.

Use the technique in the Hallicrafters S-38A and later. Provide feedback around the IF amplifier and switch it on and off.

A side benefit may be that the sensitivity is improved a bit.

The best approach is to feed back the output of the IF amplifier back to the input via a pair of series capacitors. Ground the junction to switch it off.

You won't have control over the pitch and it won't be stable.

I never tried it but you could put a 455 kHz crystal in the feedback path and make it stable.

Just read the interesting notes for improving IP3 of MC1496 from the usual -20dBm towards +20dBm by Ian Briathwaite in Radcom TT Apr. 98, also shown in Technical topics scrapbook, and the following notes by G3RZP on SL6440. As alternative Gilbert cell mixer G4COL suggest to use 2x CA3046 (=3086?) with IP3 of over +20dBm.

Wonder if somebody has tried similar increased currents with other devices to achieve high IP3?

3102. Re: SIMPLE BFO

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-21 19:38:29 UTC
From: Jim Pennell <NoSpam@killspam.com>
Message-ID: <a9v5rq$64k$1@slb3.atl.mindspring.net>
Source record: 44644

One of the problems with adding a BFO to an existing radio is that the existing radios AGC circuitry will almost certainly get messed up.

Most AM radios use a detector for the AGC which will respond very nicely to the BFO signal which will then reduce the radios gain since it is detecting a powerful signal.

So, unless you can defeat the internal AGC and then adjust the radios gain manually, you are likely to find the radios sensitivity to be shot to blazes since as far as the radio AGC detector is concerned it is seeing a VERY STRONG signal on the input.

3103. AM Transmitter Project: Follow-up

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-21 22:40:23 UTC
From: Martin Wehner <martin@cyclotomic.com>
Message-ID: <3CC33FD7.B7D2F09C@cyclotomic.com>
Source record: 44645

Hello Group-

For those interested, this is a brief follow-up to a call for help I had sent out to this newsgroup a few weeks back.

Thank you all so very much for all your help with my 160m AM transmitter project. I received a lot of really good feed-back and had a lot of people help me: thanks so much to you all.

I finally found some time to go back out to my work-bench and implement some of the circuits I had designed and tested on the computer.
Even though my output wave-forms don't look perfect, I did manage to modulate my carrier signal and obtained a pretty nice and clean looking envelope. I can easily pick up the signal on several different radios I tried.

Thanks to everyone who pitched in and helped out. I feel that I have learned a great deal and understand why the circuits do what they do.
I also picked up a copy of the ARRL "Solid State Design for the Radio Amateur" book and cannot wait to get my General class license to design, build, and operate some CW transmitters/receivers.

Thank you all for your help & encouragement!

I bought such as device as a kit from TenTec several years ago. It runs off of a 9V battery. It has a coarse tuning control which needs to be adjusted when I change bands on my Panasonic RBF-60 portable, but then the fine tuning works great for zeroing in on the SSB signals. I've mounted the little ckt board in a plastic box which I place in close proximity to the Panasonic's telescoping antenna when I use the device.

It works great. Check it out. (Probably still available on their website for about ten bucks.)

I like to use a solution called "air conditioner coil cleaner" get it at a refrig supply co mpany, comes in gallon size..Get a glass or plastic container, power in a cup or so of the solution,put the capacitor in and wash thoroughly using a bristle brush. rinse with fresh water allow to dry, it will look new..This is also good for ceramic coil forms,tube sockets, rotary switches etc..observe any cautions on the container. good luck Harold W4PQW

3108. relay that can handle 100 watts?

> available, what relay characteristics should I look for?
==========
Any normal relay (preferably hermetically sealed) with a contact rating of
a few amperes will do the trick.
I have seen plastic cased relays for RF power duties in 100 W Yeas-ic-ken
transceivers not larger than 1/4 cubic inch.
However ensure that RF power does not hit the relay contacts before these
are fully closed and use all the contacts for a single duty eg don't use one
of the contacts for control purposes.
For control purposes use (a) separate relay(s)

Coaxial relays are the obvious choice here, but expensive and not really necessary at HF. Let's face it, all the commercial autotuners use bog standard plastic cased ones.

Personally, I would go for any big chunky single throw relay. Parallel all the contacts if it's a multipole, and do not use any spare contact sets for control purposes, there will doubtless be lots of RF on them. Assuming that the relay is not going to be sited at a point of extreme RF voltage, an auto-salvage yard should yield several contenders. Remember though, that the longer the switching elements are, the less isolation you'll have, so the more RF will get into your pre-amp when on TX.

Omron make some nice compact 250V 10A SPST relays with a 12V coil, almost ubiquitous in monitor and TV degaussing circuits. These have a BIG contact gap too to cope with any back emf off the coil, although the thermistor should mean there isn't any.

Careful choice of sequencing circuitry so there is no RF on the line when it is switched will help prolong the contacts' life.

Good luck

As a general rule of thumb, dry air has a break down of about 20,000 volts per inch. The actual break down voltage depends on a lot of factors. Two pointed objects, such as the sharp corners of a capacitor plate, will break down at a lower voltage and rounded objects at a higher voltage. Humidity will also lower the voltage limit. Any dielectric, in fact, will change it. Another post suggested using teflon between the plates.

Your 5300 volts at 0.12 inches works out to a derating factor of approximately 45% compared to my dry air number. I was going to say 50%, so anything in this ballpark would probably be adequate.

Go for it! Not enough people are homebrewing these days, in my opinion.

I have done this before, and it works:

If you have a 'cheap' shortwave receiver in a plastic case try this
idea. Get a small pocket size AM broadcast band receiver (also with
plastic case) and place it next to the short wave receiver. Turn both
on and but leave the volume turned down on the BCB receiver. Tune in
a signal on the shortwave receiver. Then tune around on the BCB
receiver until you hear a beat note on the shortwave receiver. Once
this is done you should not have to touch the BCB receiver.

What I think is happening is that the leakage from the AM BCB receiver
IF on 455 kHZ is providing the BFO signal to the shortwave receiver.

The radio doesn't generate much of a 455 kc signal unless a station is
tuned in. But along the same lines, by tuning around, you may find a
harmonic of the local oscillator that will correspond with the SW freq
and provide a beat note.

Marvin,
I have used the lemon juice method several times,
and it's worked well. (lemon juice in water,
boil it till it's squeaky clean)
I usually had to clean a vfo tuning capacitor because
the frequency would 'jitter' Mostly old Heathkits.
I found that after cleaning, a small amount of STP oil treatment
on the bearings would make it work like new.
Of course, you might not want to use STP if it's in
a tank cirucit somewhere!

3117. DSP or analogic filter in RX app. What is the best ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-22 19:27:57 UTC
From: Rocco Tanucci <haganah_99@yahoo.com>
Message-ID: <1081173afa75df3b4693aae9eb7e724a.67469@mygate.mailgate.org>
Source record: 44559

Hi All,

I think that DSP filter in a receiver application it will never
beat the good analogic (mechanical or xtal filters) !!!!

In other words the DSP filter looks good in theory but when we
receive a weak signal very close to a strong signal the DSP goes
completely crazy (also with 24 bits ADC and 32 bits DSP !)

The solution is to use DSP only at AF and leave the good Collins
mechanical filter in the last IF.

This is why the most important HF transceiver HAM Manufacturing
Companies
released firstly a series of transceivers without the last analogic
filters but
then moved the DSP back to AF and restored the analogic filters !!!!

What do you think about it ???

Rocco

I built one using two Altoid tins as a case. 9 v battery fit inside.
Duct tape holds the two tins together. Tuned circuit in the
oscillator used a 455 Khz transformer as the tuned circuit. I added a
small variable cap to tune. No need to connect internally to radio.
Just put the device near the radio and wrap the output wire from the
BFO around the telescoping antenna on the receiver. It works. Not
great, but you can listen to SSB where previously all you heard was
Donald Duck. Fun, simple HB project.

3122. A sub-band for Homebrewers and Experimenters?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-23 02:59:37 UTC
From: K0HB <KAYZEROHB@ELECTRICSMOKE.NET>
Message-ID: <t64x8.2486$iQ5.232163@newsread2.prod.itd.earthlink.net>
Source record: 44564
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

With the advent of restructuring and the end of new Novice licenses, the old Novice bands will have less and less reason to be set aside for that purpose. ARRL has recommended that they be disestablished and that the phone segments of those bands be increased, and FCC is requesting comments (the reference to the petition in "RM-10413").

Wouldn't this be a great opportunity to set up some sub-bands to showcase amateurs experimenting with new technologies? You can comment to FCC at their web site (http://gullfoss2.fcc.gov/prod/ecfs/upload_v2.cgi) or by mail.

Below are my comments.

Before the
Federal Communications Commission
Washington, DC 20554

In the Matter of)
)
Amendment of Part 97 of the Commission's) RM-10413
Amateur Service Rules Governing)
Operating Privileges)
)

PERSONAL COMMENTS OF HANS BRAKOB, K0HB

OVERVIEW

These comments are in response to the ARRL proposal for "refarming" the existing HF "Novice sub-bands".

I. Discussion:

The ARRL petition does not address the implementation of new technologies as repeatedly requested by the Commission in WT Docket 98-143. It simply proposes to eliminate the Novice segments and reshuffle that spectrum among existing legacy modes. Rather than gain consensus, the ARRL polling method produced a popularity poll among several non-responsive (to 98-143) choices.

Rather than just "more of the same old stuff", I propose that the Commission take this opportunity to provide the Amateur Radio service with a new incentive to concentrate on paragraph 97.1(b) of the Commission's Rules.

97.1(b) Continuation and extension of the amateur's proven
ability to contribute to the advancement of the
radio art.

While I agree that the declining Novice license population
no longer justifies several significant chunks of spectrum
as a "reservation" for improving their Morse skills, and that
these "reservations" have outlived their regulatory purpose,
I propose that we retain these 50-year old "reservations" and
convert them to a new purpose which will ensure the future
Amateur Radio service continues our "proven ability to
contribute to the advancement".

II Proposal:

A. To "de-populate" the current Novice segments, I propose
that all Novice (and Technician with code credit) licensees
be authorized to use Morse code in the same band segments
now authorized for General class licensees.

B. I propose that the current Novice sub-bands be set aside
as a new "Experimental Reservation" for non-traditional
and experimental modes such as digitized voice, digitized
image, and other "forward looking" communications methods.

C. I propose that the current power output level of 200W
be retained for those segments, and additionally propose
that transmitters in those segments must be equipped with
auto-adaptive circuitry to reduce output to the lowest
level consistent with reliable communications.

D. I recommend that the Commission grant broad discretion
to amateurs operating in this "experimental reservation"
as to innovative modulation schemes and non-traditional
technologies.

Respectfully submitted,

H. Hans Brakob, K0HB
1610 Weston Lane
Plymouth, MN 55447-2855

You do realize that it's practically identical to the MC1350? "The
MC1349P is an improved version of the MC1350P. Featuring higher gain,
a lower noise figure, and greater AGC range; in addition, an emitter
of the input amplifier is available for bypassing."

So the pinout is identical to the MC1350P, except for pin 3. Instead
of being a ground pin, you put a bypass capacitor there with the '49.

The MC1590 is the same circuitry as the MC1350P, though the pinouts
are not the same. I've never looked closely to see what real difference
in specs there are.

Believe I have data somewhere, might scan a few pages later. The
device was supposed to be an improvement over MC1350P for Video IF
applications, but the books only shows application with +15V operation

Today I would think that it would perfectly well operate on 12V
provided that Vcc1 is dropped to +9V, but you are not certain until
you have tried it.

Bought some devices 30 years ago, since I was advised that this was an
improved device over MC1350P, but never used them because of the
"limited" application data available from Motorola

I have a Quezar power supply, circa 1975. The thing has driven me nuts for 27 years.

It started life as 4 2N3055 like power transistors, driven by a smaller power transistor that isn't made any more. The Darlington string works just fine. Big heat sinks.

But I have eternally had trouble getting the thing to work. Tried a 723, and it took off gloriously (ever see an HR-2 at 28 volts?), and yesterday tried a big zener, which is what was in there earlier. I just can't get enough current in the zener to keep the thing zenering at 10 amps.

My latest theory is that of using a LM 317 to drive that stuff.

It's a hefty beast, with a really big computer grade capacitor in it.

Anyone know of a good book on the design of such things? I have National Semiconductor application notes coming out my ears, and the ones in the Handbooks seem to have a lot of stuff that I don't need.

Please respond to jwodell@provide.net. Such a simple problem

Thanks, 73 jerry w8gnd

========
Having an ARRL handbook 1995 ,there is a circuit diagramme for a 28 V PSU
with 4 pcs 2N3055 in parallel ,driven by another 2N3055 which in turn is
driven by a 723 IC . This IC is fed via a LM317L.
You'll find it in chapter 11 , page 11.40
I am sure the circuit diagramme will also be in other ARRL Handbooks around
that year.

The circuit is obviously suitable for 13.8 V output or 50 V for that matter.
If you build / modify your PSU in accordance with this circuit diagramme ,
I can't
believe you will have any problems.

Good Luck

Frank gm0csz.kn6wh@ntlworld.com

> -Bill

Well, of course. That's why I said you had to tune around on the BCB
receiver, and once it was set you didn't have to touch it. If you
used a harmonic of the local oscillator you would have to keep
fiddling with it as you tuned the shortwave receiver.

There has to be a strong BCB station in the area for this to work, but
it does work.

3132. HB Amps

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-23 17:32:28 UTC
From: KU4YP <ku4yp@earthlink.net>
Message-ID: <MUgx8.750$607.64561@newsread1.prod.itd.earthlink.net>
Source record: 44574

hello,

is there anyone who has built a HB Amp for 10 meters? i have one of
those monoband rigs for 10 and 4 6146s and was thinking of building a amp.
not looking for a Kw, just about 200-500 watts. do not want to "work all
neighbors" hihi.

Source record: 44575

Hi Mike, I have not built one, and the only reference that
is in the shack is the ARRL handbook for 1966 (43rd)
edition, page 190-193, has a 200 watt general purpose
amp using two 6146B's that covers 3.5 thru 28 MHz.

You could eliminate the multiband components and use
the 10 meter. The power transformer is 6.3v at 5 amps,
and 800 v.c.t. at 250 ma. Not sure the output filtering
is up to current standards so you might want to do some
calculating!

Happy building, 73, Walter, AG5P

This is also known as a SN76514 and was used as a DBM in the Sartori mods for the R4C. I may have a pin out for the dip package if that will help. I looked for a TI linear book on the shelf but don't have the mfg info. Fairchild or Motorola may have also made the 76514.

have a vague impression of the 76514, do you mean they are equal? It
was some integrated 600 ohm resistors limiting the use, so I preferred
MC1496/1596 DIL devices. I have Sartori mods, maybe the reason for
buying it on the first hand...

The TL442 and SN76514 are the same part. I don't have a source for the data sheet (maybe someone has a ww.freetradezone.com subscription?), but there's a lot of applications info in "Solid State Design for the Radio Amateur."

I'm about to use one in a receiver project for the first time in several years. They are out of production, but I was able to order 10 of them from Rochester Electronics under the SN76514 part number just a couple of weeks ago.

Made some experiments with a circuit which seems to have few problems.
Earlier tried some published circuits which didn't work at all. It is
always a problem that amateur constructions may not be reproducible,
but my circuit has been tested and is used in production at a nearby
factory who needed a simple VCO. So it is at least tested by two
persons with success.

Transistor is 2N3904 or better, a HF type like MPS918, 2N2369 or other

If you are interested I can mail you the circuit and text as two gif
files (max 47kB)

Common problem. I have the same with PCB design software designed to run under DOS. Worked Ok with Windoze 3.11 but as soon as I shoved in 98 and a graphic card, all the text looks like something Dr. Spock would write.

My solution 1 - software - try starting the computer with DOS, then run WIN.EXE in your WINDOZE3 directory. I have copied all the Win3.11 files to another windoze directory and can start either.

My solution 2 - Keep an old 486 Win3.11 computer aside for this sort of thing.

I do both!

It will be 7 weeks tomorrow, someone mentioned it took up to 2 months, if the goods aren't here friday next week, I'm gonna try to contact the guy, if I don't get a reply, I'm filling a complaint at the postal office, so they can get my money back. Every day that passes I find it harder to believe the US postal service is to blame, neither do I believe the package would be sitting at our customs, not for this long.

The MC1496 is far-and-away the best doubled-balanced modulator integrated circuit (or receiving demodulator) ever invented. It's common sense.

I have no wish to get involved with argumentative, ill-educated nit-wits who think they know better.

Reg, G4FGQ.

I don't know if you noticed, but Dan's Small Parts and Kits web site was updated on 04-09-2002 (that would be April 9, 2002 for international readers).
<http://www.fix.net/dans.html>

3153. How does a noise canceller work?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-25 16:32:56 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0204250832.b5144c5@posting.google.com>
Source record: 44595
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

There are several noise canceller products on the market, such as the MFJ-1025 and MFJ-1026.

http://www.mfjenterprises.com/products.php?prodid=MFJ-1025

http://www.mfjenterprises.com/products.php?prodid=MFJ-1026

Both of these products are said to have the ability to remove local AND DX noise sources. This would be a miracle on the lower bands on summer nights, when distant lightning strikes wreak havoc on the bands.

From what I understand, it connects to a signal antenna (your regular transmit antenna) and a noise antenna (a second antenna). The signal antenna picks up the weak signal and the noise. The noise antenna just picks up the noise. You amplify the noise from the noise antenna so that it is the same intensity as the noise from the signal antenna. You adjust the phase of the noise from the noise antenna so that it is 180 degrees out of phase with the noise from the signal antenna. The received RF from the signal and the noise antennas is added, the out-of-phase-noise components cancel out, and only the RF signal reaches the receiver.

The BIG question: Why doesn't the noise antenna receive some of the signal as well as the noise? Even if the noise antenna is much less efficient than the regular signal antenna, wouldn't this diminish the noise received as well as the signal received?

Hi Jerry

For a cheap and cheerful input, take an ordinary 7812 1A regulator and put 4
of any silicon diodes between it's ground pin and ground. This will give you
about
14.8V on the input to the Darlington chain and thus about 13.4V out

Very reliable, much more so than a pot. You may need a small heatsink on the
7812
but I doubt it.

Good luck

My understanding is that there is a difference in phase between the
desired signal and that of the noise given their different source
locations. That gadget can be tuned for either one. MFJ explains it
pretty well....

Jason, most of these devices work on a very basic principal, Two signals 180 degrees out of phase of equal amplitude will cancel each other..This noise on your receiver is a broad signal riding on the wanted signal, by picking up this noise on another antenna,running it through a seperate receiver, adjusting the amplitude and phase , it will cancel the noise. before it gets to your receiver. on most noises they work pretty good, requires a bit of practice to get it right,also the interference must be steady for the noise cancellor to really be effective...73 Harold W4PQW

3160. Reducing PLL noise - active noise cancelling

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-26 00:51:10 UTC
From: Richard Hosking <zaprichardh@iinet.net.au>
Message-ID: <3cc8a2b3$0$11736@echo-01.iinet.net.au>
Source record: 44502

There were some posts in this NG about using an active noise cancelling scheme to reduce the noise output in power regulators (Wenzel).
Is it possible to apply this scheme to a PLL loop filter?
I guess the problem would be bandwidth - obviously there would have to be a low pass effect to allow the PLL error voltage past - still it should be possible to reduce the contribution from phase detector noise which is dominant within the loop bandwidth.
Anyone got any excperience of this?

Richard

Look for a relay where:

- The moving contact isn't connected with wire (low stray inductance), and

- The moving contact is isolated from the magnetic armature (low stray capcitance).

The Potter-Brumfield "RK" series is a good example. Its leaf spring contacts have low inductance and are well separated from the armature metal. Their T90 series is not, because the moving contact is mounted directly to the iron aramture.

Other manufacturers have similar parts. Go to the surplus store and have a look at the goods before buying.

Now I'm really cornfused! Here's what W1RFI sent me from ARRL....

Hi, Hans,

I checked into this a bit at work today. Apparently Compact software had
been sold to Ansoft. Ansoft chose not to continue to support ARD, probably
because they felt it competed with their present product line. The program
does not run on 95 and 98 because it would need to be recompiled. ARRL does
not own the rights, but had sold it under a licensing agreement.

Ansoft does have a freeware student version that does most of the things
that
ARD used to do.

For info, see:

http://www.arrl.org/ard/

Ed doesn't have it _quite_ right. ARD runs on some W98 systems but not on others. It's a 16-bit Windows (3.1) program that its manufacturer was uninterested in maintaining it as newer versions of Windows came out. (What, you thought Windows was really backward compatible with older versions? :-) So, if it runs on your machine running Win98, great! But it may not.

Serenade SV (see the URL Ed cited, below) is probably your best alternative.

They are the same IC. I think Texas Instrument was changing their
numbering scheme around the time the IC came out, which is why
two very different numbers reference the same IC.

I've never seen a data sheet for the device. As I've said before,
even when it was being made, it wasn't a commonly available part.

It was my impression that when people used it, it was because
it needed few external components, compared to the
MC1496. Certainly, the articles I've seen that use it, only
mention the simple circuit. Peter Bertini, though, once said it had
better signal handling capability. I was never sure if that was a guess,
or if he'd seen the data sheet.

To reference your other thread, I've wondered a bit about biasing.
One might think there is a limit due to the transistors used in
the MC1496.

Doug DeMaw wrote one or two articles about using an RCA transistor
array, or maybe it was a dual differencial amplifier, for a double
balanced mixer like the MC1496. I don't think he ever said why
he didn't use the 1496. This would have been about 1974, and he
was modifying a direct conversion QRP rig, maybe a Heathkit. I

think "Solid State for the Radio Amateur" has something along these lines.

I've thought about building up one using just discrete transistors. After all, hams got by without ICs for decades. It would certainly be easier than finding a transistor array.

I did a search for the TL442 data sheet the other day, and like you, found nothing. However, I did find an intriguing page by someone playing around with Gilbert Cell mixers using discrete transistors. I've only glanced at it, but it might be of interest: http://www.intio.or.jp/jf10zl/gil.htm

3166. Re: TL442 data ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-26 04:25:32 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3CC8D6BC.86328F67@eznec.com>
Source record: 44508

Years ago, I was investigating the possibility of using an MC1496 for an application it wasn't intended for. I got samples from a number of manufacturers, opened up the cans or had the plastic packages dissolved, and took a good look at the dice. I found that there were at least three, very different, chips being sold under that part number. Some inherently didn't have really good balance because of unsymmetrical crossovers and the like. The signal handling and transistor dissipation capability would also have been very different because the transistors differed widely in size among the various chips.

About a year after I did the investigation (and decided not to use the part), I got a call from the company's component group asking for the unpackaged chips I had. Seems that one or more of the suppliers had changed the layout in a way that caused it to quit working in one of our products.

The moral is that no matter how much you learn about one manufacturer's part, you still don't know about the others. And you don't know what even that manufacturer's future pars will do. If you're only building one or two units, no problem -- just design them around the parts you have on hand. But if you're using the chip in an unconventional or unspecified way, don't count on anyone being able to duplicate it.

Search on the correct spelling (Tektronix) and you'll likely have better luck. Besides eBay, have a look at the manual resources listed at http://www.reprise.com/host/tektronix/home/default.asp. This is not a particularly rare bird, so it shouldn't be too tough to come up with a manual for it.

It may do so - so what? If the desired signal is that strong, then
reducing it a bit is not going to hurt.

Or you can adjust the noise antenna gain until the desired signal is
not reduced. The result would be a compromise on noise reduction.

The whole system works when there is a different S/N ratio between
the two antennas. If they are the same - as is often the case with
DX noise, then there is little or no noise reduction possible by
such simple signal inversion.

I remember the TNS well. Wish I could find the schematic for it now - seems to me it used a 12AT7 or something similar. Anyway, I had a Gonset Triband converter, and was running the famous "28/9" transmitter in a 1934 Ford sedan. Those were the days.

From my understanding of how this is donee, the comments about phase
cancellation are correct. However, you should normally locate your noise
antenna(s) as close to the noise sources as possible. In this way, because
of the proximity to the noise source they are picking up much more of the
noise and less of the wanted signal (If they are placed within a building
for example)

Richard,

I followed the discussion on pll loop noise between you and John with great interest. The conclusion seems inescapable - to get good performance, you must have a good vco.

The schemes to reduce power supply noise may have some effect by reducing the supply noise to the op amp in the loop filter, but most op amps have good common mode rejection so there may not be much benefit.

Reducing supply noise may help in reducing jitter in the dividers and pll output signal, but I suspect divider jitter may be the dominant problem. If so, not much can be done.

There may be another way to eliminate the effect of jitter. Recent work on the binary sampler shows it removes timing jitter the same way as amplitude noise, as predicted in the theory page at

http://www3.sympatico.ca/add.automation/sampler/noise.htm#morenotes

For an example, while debugging a DDS-controlled TDR prototype, we measured about 100ps timing jitter in the step generator. However, the sampler easily showed the 160ps risetime of the step generator without the noise. This is shown in the TDR plot at

http://www3.sympatico.ca/add.automation/sampler/results.htm#binsamp

The binary sampler should also improve the noise performance in a pll in the same fashion, as shown in

http://www3.sympatico.ca/add.automation/sampler/noise.htm#micpll

As with all sampling pll's, it would need assistance getting locked, but if the vco phase noise were low enough to keep the loop locked in

the narrow bandwidth that you and John discussed, it should give
improved noise performance.

I would love to get my hands on one of your pcb's to try it, but alas,
I do not have a spectrum analyzer to measure the result. However,
there are other methods of measuring phase noise that may be suitable.

Regards, Mike

>Amateur."

Rather than figure out all those [#$%^&] anti-spam email addresses, I've
put the datasheet (that I got off Freetrade zone before they switched
it to subscription) on my FTP directory.

ftp://ftp.eskimo.com/u/m/mzenier/TL442C.pdf
Don't expect it to be there forever.

My question is what the heck is a SN16913P ? This appears to also be
a balanced mixer, and is used in the synthesizer in the Kenwood R-1000
reciever, from about 20 years ago. (That's why I got the TL442 datasheet,
to see if it was the same thing, but the pinout's different).

Source record: 44520

The typical limiting item for phase noise in a PLL is the performance of the VCO itself.

There is a limit to the noise reduction the dividers and phase comparator can obtain and that is degraded by the number of divisions prior to the phase comparator.

Figure on 20* log(N) where N is the number of divisions in the divider logic. with a division of 0, the noise floor of digital logic and phase comparators is around -150 dBc in a 1 Hertz bandwith at the best of times.

With a divide by 100 for example, then 20 * log(100) = 40

That is reduces the -150 dBc to get -110 dBc as the best possible phase noise in the loop bandwidth.

So, that dictates the loop bandwith... Where the performance is better of the 'freerunning' VCO phase noise compared to the noise level the dividers/comparator bottom out at.

There is no practical method to use 'active noise cancelling' since the noise is a random phenomenon and originates in the VCO itself.

The best choice is to reduce the tuning range of the VCO and use a high Q inductor in the VCO resonant tank. In this design, the tradeoff was to use a single VCO which simplifies the design tremendously, but it also means the VCO is fairly noisy.

He could have used several VCOs and gotten better wideband phase noise but that would have been a lot more expensive and made the circuitry much more complicated.

Design tradeoffs are always a compromise between cost and performance. Sigh....

The post office will not help get your money back. If there is a
persistent pattern of non-shipment of goods, they will turn the info
over to federal agencies for possible prosecution. That is all the
help you will get.

I have been through this myself. The fraud statutes are basically
toothless for small time crooks.

That is not true. The method works in on any type of noise where the
sense antenna receives a different signal than the main receive antenna.

From: Jim Larsen - AL7FS <AL7FS@ARRL.NET>
Organization: CranioSacral Therapy - ref: http://www.upledger.com

I am glad you enjoyed my website, at least I think that is what you are referring to. Congratulation on your new license. It can open up almost unlimited doors for you to explore. I have been a ham since I was 16 back in early 1965.

Beginner transceiver.

I don't know your financial situation but here are a few thoughts.

My favorite link page: http://www.njqrp.org/data/links.html I like it so much I made it my Home Page on Netscape.

Check out Doug Hendricks suggestions at http://www.qsl.net/westfla/kits/ Excellent logic on his suggestions but be aware, some of the kits may or may not be available. I think at least the first four suggestions are good but did not check further. By following Doug's suggestions you can move into progressively tougher kits.

Consider buying a good soldering iron. A Weller WCTPT is a good one. You want about a 675-700 degree tip. As a new solder person, you will need to remember the 3 second rule. Don't stay on a point too long or you will damage things. I wouldn't go below 650 degrees. If money is not a big issue, I like my Weller with temperature control. A good iron will cost a minimum of $90-100. Anything less and you may be disappointed. Also pick up some desoldering wick (a wire mesh braided thingy that sucks up solder when you heat it while on a bad solder point) for the occasional mistake. Do a search on http://www.google.com for "desoldering wick". Of course buy good solder, Rosin core only. Go to http://www.elecraft.com/ , click on Tech Notes Articles and then scroll down to the Soldering Tutorial. Also read the article about Ask Dr. Solder. You can learn what size of solder to buy from these

articles. You can also glean some good points from
http://www.qsl.net/ve3mcf/elecraft_reflect/Building_Notes.txt
and http://www.io.com/~n5fc/rfprobe1.htm

The Pixie:

Check out http://www.qrpp-i.com/index.htm and especially the Elmer 001 course info. The Tiny Tornado costs more but is a better radio. I suggest you buy the HSC Electronics (cheaper) version and build it for fun and for low cost. You can learn a bit how to solder with it and it may be fun to play with. It is not, however, a serious rig for using regularly. You would want a crystal on 7.040 which can be purchased from the NorCal QRP club for only $3.00.
http://www.fix.net/~jparker/norcal.html Click on kits and then scroll down to the info on crystals.

The next rig I suggest is from Small Wonder Labs.
http://www.smallwonderlabs.com/ Buy a SW40+ . You can buy this rig for $55-60 without a case or about $85 with a case. If you are new to this, the case would make sense. I bought the case as you probably saw in my article on my website.

This is a good starter kit and there is a whole class online to teach you all about it as you build. The class was called Elmer 101 and is found at
http://www.qsl.net/kf4trd/faq.html and
http://www.xcvr.com/default.asp?view=elmer101

Learning code.

My daughter used the ARRL CD for studying. I suggest you might try it. It is the CD used in the K7QO course which is what my daughter used. Worked well. K7QO strongly suggest the CD over the tapes.

Review:
http://www.arrl.org/FandES/ead/learncw/
http://www.qsl.net/k7qo/ scroll to "K7QO's Online Code Course - Beginning to Receive "

Best of luck, Lee, and I hope you continue with your CW. I have never gotten much above 20 wpm on my code but I still enjoy it and use it 95% of the time on HF. I usually operate around 15-18 wpm.

Variations in amplitude or phase of the interfering or wanted signal
(say by aircraft reflection) are unlikely to result in an identical
change in both the sense and main aerials. This will result in
degredation of the output by a greater or lesser extent.

They said that when any problem arises, they will pay me back my money, and
I don't have to think of anything else, they'll handle any actions or
whatever that have to be taken to get their money back (from there on, it's
their money, because I got mine back already) :)
Anyways, I'm still in the believe that the goods will get here before it
comes to that.

Google is your friend (especially the Google cache). Just type in the
part #, with or without the -P suffix, and you'll find at least some
data. Sometimes this trick will turn up the whole data sheet for an
obsolete part on some obscure university server, but the TL442 is an
exception.

In the SN16913P's case, there's at least one cached copy of an old
Tripod site with the pinout.

Hey gang,

I have no personal connection with these guys other than being a happy customer, but I saw these on the website and thought others might benefit.

Ocean State Electronics is selling 65Mhz O Scope probes for $13.95 (3 pos switch X1, REF, X10) and they fit all scopes with BNC connectors. They also have 100 Mhz probes for $26.95 same config but with a 5 piece accessory kit.

I'm not a happy customer of OSE. His method of saying 'out-of-stock'
which was about 6 out of 8 items was to not respond at all to an order
placed via fax. It took 30 days to get an email response explaining
this.
But, I hear others have had good experience with them.

I have been looking for a broad band noise generator but so far I have been
un-successful. The HP noise diodes are very expensive GG's and I have
doubted that the NE555 timer chip could produce a predictable noise spectrum
output level. Your claim of a flat 0dbm output is a welcome surprise.
Question; is it possible to provide a predictable output level or at-least
calibrate the noise level output without an expensive spectrum analyzer or
other expensive equipment ?
I would be interested in your noise generator planes.
Thanks in advance for your comments.

3202. FS: Books on Radio Antennas

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-28 13:08:10 UTC
From: oldbooks78@aol.com
Message-ID: <20020428090810.07218.00006417@mb-dd.aol.com>
Source record: 44544

I currently have the following books for sale on radio antennas. Postage is $2 for the first book and $1 for each additional item (within the US, at cost elsewhere). The books are:

Moxon, L.A. "HF Antennas for All Locations" published by the Radio Society of Great Britain, 1991. ISBN 0900612576 The 260 page softbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. A thorough treatment of HF antennas. Available for $9.

Straw, R. Dean (editor) "The ARRL Antenna Compendium (Vol. 6)", Newington, CT, U.S.A.: American Radio Relay League, Incorporated, 1999. ISBN: 0872597431 The 200 page softbound book is in fine condition, fresh and clean inside and out. All new articles (43 of them) on antennas, transmission lines and propagation - projects to build and new approaches to explore. Includes a CD inside the rear cover with the source data for modeling many of the antennas. Available for $12.

Straw, R. Dean (editor) "The ARRL Antenna Compendium (Vol. 5)", Newington, CT, U.S.A.: American Radio Relay League, Incorporated, 1996. ISBN: 0872595625 The 200 page softbound book is in near fine condition, fresh and clean inside and out except for a square neatly cut from the lower corner of the blank rear end page (it may have been a coupon or order form). Includes a diskette inside the rear cover with the source data for modeling many of the antennas. Available for $9.

Straw, R. Dean (editor) "The ARRL Antenna Compendium (Vol. 4)", Newington, CT, U.S.A.: American Radio Relay League, Incorporated, 1995. ISBN: 0872594912 The 204 page softbound book is in fine condition, fresh and clean inside and out.Includes a diskette inside the rear cover with the source data for modeling the antennas. Available for $10.

Hall, Gerald L. (editor) "The ARRL Antenna Compendium (Vol. 3)", Newington, CT, U.S.A.: American Radio Relay League, Incorporated, 1992. ISBN: 0872594017 The 236 page softbound book is in fine condition, fresh and clean inside and out. Lots of useful information on radio antennas. Available for $9.

Hall, Gerald L. (editor) "ARRL Antenna Compendium (Vol. 2)", Newington, CT, U.S.A.: American Radio Relay League, Incorporated, 1989. ISBN: 0872592545 The 208 page softbound book is in very good condition, fresh and clean inside and out. Available for $9.

Hall, Gerald; Paul Rinaldo; Maureen Thompson (editors) "ARRL Antenna Compendium, Volume 1", Newington, CT, U.S.A.: American Radio Relay League, Incorporated, 1985. ISBN: 0872590194 The 175 page softbound book is in fine condition, fresh and clean inside and out. Available for $9.

Erwin, David G4LQ1 "HF Antenna Collection", Radio Society of Great Britain, 1994. ISBN 1872309089 The 233 page softbound book is in fine condition, fresh and clean inside and out. Available for $9.

Orr, William I. "The W6SAI HF Antenna Handbook", Hicksville, NY, U.S.A.: C Q Communications, Incorporated, 1996. ISBN: 0943016150 The magazine-sized softbound book is in fine condition, fresh and clean inside and out. Available for $9.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

3203. ER and Vintage Field Day June 8 and 9

Newsgroup: rec.radio.amateur.homebrew

From: John Dilks <oldradio@worldnet.att.net>
Message-ID: <3CCBFEAE.74AB@worldnet.att.net>
Source record: 44545

To all BA'ers,

Electric Radio Magazine is promoting a Vintage Field Day this year on June 8th and 9th. To help generate interest, I put up a vintage field day web page, using 16 photos of an early 1950's SJRA field day.

If anyone has more information to share on this year's VFD, please email me directly and I'll add it to the page. Please copy Barry at ER too.... er@frontier.net

I hope you enjoy it. The link is below..... you'll find it on my ARRL Old Radio column web page.

73's de K2TQN, John Dilks

Hello Mike,

I think that you will find that the plate capacitance of four 6146 tubes
will be too high for a decent Q on ten meters. I would look at
something like an 813 or a 4CX250B.

==========

I have made broadband noise generators by starting with a 50 ohm resistor
to ground and then cascading amplifiers to get enough gain to show the
broadband noise.

This works and is VERY broadband.

==========

However, it has been my experience that making it all truely flat across
the band up to 1.3 GHz is difficult. Generally, there is slight tilt in
the gain of each stage and the effect is multiplied by each following
amplifier stage adding it's own slightly higher gain at low frequencies
to the total signal.

For just about any ham radio application, this slight rolloff can be
ignored. In any given segment that is being looked at through a filter
or some such the noise is flat for most practical purposes.

As for the power output of the noise generator, the TOTAL power output
is the sum of all the noise. This integrated total power adds up fast.

So, to keep linearity and avoid clipping the noise peaks, the power in
any given narrow band will be relatively low.... The total power output
of my noise generator is -3 dBm after the output stages 3 dB attenuator.
I use this attenuator to maintain a 50 ohm non-reactive output for the
noise generator.

I use a MAR-4 output stage so it's about 12 dB below the 1 dB compression
point of the amplifier. That allows for fairly high noise peaks while
keeping the noise linear.

You can easily built a similar system, I use MAR-4 stages and cascade enough of them to get a total gain aroun 100 dB. I add 3 dB attenuators here and there in my amplifier chains to keep the system 50 ohms and more or less non-reactive.

Otherwise, the 'S' parameters of the MAR-4 stages interact and start to take the effective impedance away from 50 ohms to some degree. THAT adds to tilt effects due to mismatch. Besides, they give convenient points to change the gain as required to get the total system gain I want.

==========

Now, this is a LOT of gain, and so I recommend breaking up the board into separate modules, with shielded sidewalls to avoid feedback. Also, watch out for power supply wires giving feedback coupling.

I use separate small Printed circuit boards to maintain total isolation and shielding. This system can and will pick up any signal off the air and amplify the heck out of it....

Oh yes, be very careful to control the DC voltage feeding the noise generator, small changes in the voltage will cause the noise level to go up or down a bit as each amplifiers gain varies slightly.

> TIA,MM

In general, that's not going to happen. A sound card driver uses DMA to transfer entire blocks of samples at once with infrequent interrupts. A PC speaker driver uses very frequent interrupts or polling techniques to produce sound by toggling the speaker cone directly.

Years ago, there were a few hacks to make sound cards with no digital audio support (like the original Ad Lib board) play digitized sounds, but they sounded awful and were very hardware-specific. I'd be surprised if they worked at all on modern machines.

Some older sound cards (the Media Vision Pro Audio Spectrum series comes to mind) had the ability to trap accesses to the PC speaker port and play the sound through the speakers. I am not sure if any modern cards still offer this ability.

You might have a look at the "AIL Version 2" link in the table of contents on my site (below) for a commercial-quality sound-card driver package for real-mode DOS.

IFR-1200a this version just has a oscilliscope, generates pl tones,dpl. No dvm option everything working. will have a pic soon to post or email. All I have is the cord. Might be able to get a maintenance manual if I find it. Does not have tracking generator or spectrum analyzer. This is an 1200a not 1200s. It does duplex generate, deviation meter freq meter, 1k tone, sinad. Other than that it works excellent. and looks good not beat.

$2000.00 you ship cost about $40 ups ground.

I could imagine placing the noise antenna right in-between the PC and
the TV, while the main antenna would be between two trees outside of the
house.

I'm pretty sure the noise antenna will have a very different S/N ratio
than the main antenna ;)

Hello

Is it possable to take two transformers with full wave center tap
rectifiers on each transformer and then connect the outputs of the
rectifiers in series to double the voltage?

The transformers are not of the same type. one is 720-0-720 and the
other one is 500-0-500.

Next question. Is there a way to find out the working ampere rating of a
transformer? There are no markings or numbers on them.

It would depend on the phase relationships between the desired signal and the nulling antenna. Also, the amplitudes and phasing must exactly correct to achieve a perfect null. It is doubtful that you would achieve a perfect 180 degree phase relationship and exact amplitudes for both the desired and unwanted signals.

Peter

Just a comment - adjusting the two controls on a noise canceller has precisely the same effect as swinging the polar diagram of a two-element antenna around until the null lies in the same direction as the noise is coming from.

The two elements, of course, correspond to the usual antenna plus the 'noise' antenna.

<snip>

I was about to ask the same thing. I've got two 25 amp 12 volt transformers and I want a 25 amp 24 volt power source for a high torque permanent magnet DC motor controller. I've put a schematic at http://www.ilos.net/~eng/psupply.gif

My initial idea is to make one transformer power the positive side and the other power the negative. I've got lots of questions about how thick my rubber gloves should be in order to touch this thing while it's plugged in. I've tried to cover in-rush current with a resistor/relay on each side. The regulator portions are straight off of the LM723 datasheets (i.e. the floating positive and floating negative configurations). The positive side pass transistor configuration comes from the 10 amp 28 volt supply described in the ARRL handbook and uses 2N3055s. The negative side is just the complement using MJ2955 PNPs (or equiv.) instead.

My application requires a bit of circuitry to handle the problem I've been having (i.e. cooking LM723s like their going out of style) when I reduce speed too quickly. The high wattage zener and power resistors on each side of the output are intended to dissipate a moderate amount of "generator" energy from the motor. The PMC 1505 PWM controller board I'm using has the very annoying feature that it passes the energy back to it's power input terminals to recharge lead acid batteries, etc during deceleration. With the ARRL handbook circuit, the LM723 goes up in a puff of smoke.

You're welcome to any/all of the ideas here, but I too am looking for comments and suggestions from anyone who actually knows what they are talking about.

Mike

Although TV sets and computers are often a source of noise garbage
nowadays, I don't think that this gadget is quite intended as a cure for
that. It probably would work to some degree, but the noise from a
crappy monitor, or other computer cnx might be more easily addressed in
other ways.
Folks with decent outdoor antenna configurations don't seem to suffer as
much from computer noise as the guy with a new plastic portable radio
inches from his computer.
The efficacy behind the MFJ type of product is solid but it ain't a
miracle box.
-Bill

Hi OM,

0 dBm at any frequency over the range you specify is extremely
unlikely; that or the "rest of the story" has yet to be told.

Noise is generally specified in terms of 1 Hz bandwidths or in terms
of SQRT(Hz). When you look at the extremes of the frequency range and
the power level, 1 mW, it is highly unlikely without a noise source
pumping power well into the Watts range. 1W spread across 1 GHz at
1mW level would only work for bandwidths of 1 MHz - highly improbable
once you get to any IF but for the most uncommon of gear. If we were
to compute on the basis of 10 KHz IF bandwidth (being generous), the
source would have to supply 100W of noise. There are not many stable
1 GHz bandwidth amplifiers available with 1W into 50 Ohm outputs that
are also within the pocketbook of an amateur (but I would love to
discover a source of them - perhaps for cable TV distribution amps).

More likely is something several 10's of dB below 1 mW.

Jason,

Make it simple and build the source as designed; then calibrate it
against a receiver compared band by band with a source of known power.

It is even simpler than that. You could do what you suggested but you don't need the second set
of rectifiers. Picture a standard full wave rectifier circuit with the transformer center tap being the
negative output and the junction of the cathodes of the rectifiers as the positive output.
Break the junction of the two cathodes and hook one cathode to one side of the other
transformer and the remaining rectifiers cathode to the opposite side of the second transformer.
Now your positive output is the center tap of the second transformer. Then negative output
remains the center tap of the first transformer.

The only thing to watch out for is that the insulation on the two transformers can handle the
increased voltage. At the levels you are looking at it should be no problem. With lager
transformers in the several thousand volt range, sometimes the center tap needs to operate close
to ground because of the way the transformer is wound.

You need to get the proper phase of the primaries so that the voltages add or else they will
subtract and you will only get out what the difference is between the two transformers.

If both transformers were the same voltage, as another poster asked about, you could just hook
one end of each transformer together and run the remaining open end of each transformer to
each rectifier as you would with a single transformer. By having then in series this way you do
not use the center taps. Your new center tap is the junction where you hooked the two
transformers together.

I'm trying to find a couple of articles on high dynamic range mixers. I did
a search on the ARRL site and came up with two articles, both from 1999
March/April and Nov/Dec. The article is titled "High Performance Homebrew
Transceivers" in March/April but didn't get article name of Nov/Dec.
Would anyone happen to have those two .pdf files?
I sure would like to see those articles but I'm not a ARRL member, if
someone could help me out...
Thanks in Advance!
Mark

That is quite a lot of gain.

An ideal resistor at room temperature would produce -174 dBm/Hz noise
density and amplified by a noiseless 100 dB amplifier chain would set
the output noise density to -74 dBm/Hz. If the noise bandwidth is 25
MHz, the total noise power would be 0 dBm. The MAR-4 has a quite flat
gain well above 1 GHz, so the total power would be at least +16 dBm,
well above the 1 dB compression point of the last MAR-4. To get 100 dB
of raw gain from a string of MAR-4s (gain 8 dB), 12 devices are
needed.

When using the mediocre noise figures and low gain of the MAR-4, the
equivalent noise power density at the first amplifier input would be
something around -169 .. -165 dBm/Hz and with 100 dB gain and 1 GHz
bandwidth, the last amplifier output would be about +25 dBm. Thus, in
order to maintain the 12-14 dB headroom at 0 dBm, the total gain must
be attenuated by 25 dB. With 12 stages, that would be about 2 dB
attenuation for each interstage coupling. With a net gain of 6
dB/stage, in order to calculate the equivalent input noise power, at

least the first few stages must be included in the noise figure calculations.

It might be a better idea to use some higher gain lower noise figure device as the first stage, thus the noise from the input resistor would be more dominating and thus, the temperature and supply current dependency of the first amplifier would have a smaller effect on the effective noise figure.

If the noise is needed only for the amateur bands, it might be practical to insert some selectivity before the last (few) amplifier stages, thus limiting the noise bandwidth and the total noise power output.

3226. wireless serial link (possibly off-topic)

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-29 08:27:35 UTC
From: Torfi <torfitorf@yahoo.com>
Message-ID: <3ccd040b$0$14913$9b622d9e@news.freenet.de>
Source record: 44468

Hello!

I�m currently tinkering with the idea of a digital remote monitor and looking for input.
Here�s what I want to do:

My garden is about 500 meters away from my appartment. I want to implement a method of remotly monitoring various moisture-levels. I already built the remote sensor using a PICmicro microprocessor, which outputs the data as serial data (RS232 compliant using max232) and works fine when connected to my laptop via cable.

As I can�t run a 500 meter cable to my flat, I�d like to bridge the distance using radio (no line of sight, some trees and a house in between). I�ve already played around with the 433MHz remote control units from Reynolds, but they are just too weak and also too expensive to want to put in an unsupervised area...

So... I�m looking for a way to transmitt a short burst of serial data every 5-10 minutes at around 1200baud (300 baud would be fine, too) across a radio link about 500 meters... I would like to use a license-free band (possible RC-model frequencies or 11m?)

Does anybody have any weblinks about how to modulate / demodulate the signals, and also how to build a good and small transmitter/receiver that doesn�t interfere?

It would be great if the transmitter/modulator could fit inside an altoids-mints box, as that would match my sensor set-up :-)

all comments welcome!

greets,

Torfi

or you could consider a suitable wireless wan card ?

the functionality would definatly work, and with proper antennas, I might
even get the distance (although no line of sight might cause problems at
those frequencies?)...

...but it's just too expensive.... I'm afraid someone might go and steal the
equipment from my garden and would like to minimize potential costs of
rebuilding...

...also, the power-usage is too high... I have no powerline in the garden
and will have to run off (rechargable) batteries.

I have programmed my little microprocessor system to go to sleep mode for 5
minutes, then wake up and send the information and go back to sleep,
allowing the set-up to potentially run for weeks without a fresh
battery...(depends on the ammount of current drawn by the moisture sensors
and then of course by the radio...)

IME, garden-variety Zener diodes, from 5-8 V, 1W or less, make FB pink-ng's.

Following the diode with a microwave-chip or 2-3-high-hfe-transistor
RC-coupled amp will yield enough pink-noise to give the neighbors problems.
If you're 'lucky', one or more stages in your amp will be over-driven wrt
base-emitter voltage swing, perhaps shortening its life, but giving even
more noise ;o)

Yes, the gain is somewhat excessive... But that was why I added some
interstage attenuators.

I used MAR-4 for the simple reason we have them in stock, but I do
like your suggestion of lower noise stage on the input section.

However, I will have to look at the frequency response of the higher
gain low noise stage.

The higher the gain, typically, the lower the internal feedback and
hence usually mose slope across the frequency band.....

I appreciate your comments, and I will take a close look at it, since
I am in the midst of building another noise Gen.

Hey Torfi-

Check out http://www.rocket-roar.com/BWCM/toc.html.
Look at "Chapter 4 - Design Project 3: 900MHz Automatic Error-Correcting Data Link"
I have built something very similar in the past, but never bothered to put up such a detailed write-up on my web-site.
The error correction they use may be overkill in your case, but I am sure that the data presented in the write-up will help you get started.

One thing I'd like to point out is that the remote control units you used from Reynolds are right smack dab in the middle of the 70cm Amateur Radio band.
If at all possible, it would be preferable to use a module at a different frequency.

Good luck!

The problem with that approach is the large number of cascaded gain
stages required, which means that the passband roll-offs of all the
individual amplifiers will add together (like adding extra poles to a

low-pass filter). If you start from a higher-level noise source, you need fewer amplifier stages and the noise output will hold up better at the high-frequency end.

There are no real worries about building an avalanche diode noise source with a flat frequency response up to at least 1GHz - it will produce 30-35dB more noise than a resistor, and give you a flying start in generating significant power levels of noise.

But I do strongly recommend using the B-E junction of a UHF/microwave transistor as the "diode", because the parasitic inductance of the stripline package is lower than that of *any* wire-ended device. With careful construction - chip components and zero lead lengths - you can take the flatness of the noise source almost for granted. (Been there, done that, and had them tested against commercial noise sources.)

The MFJ unit works quite well against broadband white noise radiated by the switching power supplies of recent RCA large screen TVs. The trick is to position a noise antenna so that it receives a signal at least as strong as that received by your station antenna. These power supplies radiate a very strong broadband signal, and I found it necessary to position an antenna a couple of feet long very close to the TV to get the required signal strength on the noise input. It was then possible to almost completely eliminate the noise by adjusting the phase and gain controls on the MFJ. For this type of noise, I'd have to say that it is, indeed, a "miracle box". Anyone with an RCA TV who thinks he doesn't have this problem should try unplugging it sometime (not just turning it off).

I've found the box not very effective with noise emanating from the PC monitor. Reason? The noise antenna picks up many more signals because of its proximity to the monitor, and those same signals are not all heard on the station antenna. In that case, you'll never be able to null the monitor signals, but the MFJ will do a nice job of amplifying them for you! If your noise antenna is outdoors and positioned so that it picks up monitor signals of about the same strength as your station antenna, it ought to be able to null them quite well.

Where can I find a schematic for a noise canceller for HF? I would
like to homebrew a noise canceller/preamplifier that would be similar
to the MFJ-1026. (Unfortunately, the MFJ manuals available online
don't include the schematic.)

I would particularly appreciate an explanation on how the various
parts of the circuit work (noise amplifier, noise phase shifter,
signal preamplifier, filters, etc.) and the transformer specifications
I need (so that I can use something available to me).

This looks like a nice noise blanker circuit and I have saved it for future reference; however, it doesn't answer the original poster's question, "Where can I find a schematic for a noise canceler for HF." He's talking about the RF phase cancellation device like the MFJ 1026. I'd be interested too.

Ian, that is a very good point. I ran some computer simulations
on my first design and I found I had to reduce the coupling capacitors
to "more or less" flatten the response.

If I am to believe it, I should see less than 1 dB gain variation
across the band....

Of course, it is not adding in various real world rolloff factors
and so I anticipate I will see more than that. I did try to add in
the parasitic elements of the coupling capacitors and the decoupling
DC feed inductors and so on but based on experience I know it will
be worse than the simulation.

I have never tried an avalanche diode using a microwave transistor
and I will see what that can do. I think I have some MRF901 around
here somewhere.

I appreciate the suggestion and I will give it a try. Starting
with that sort of noise will help a lot in making it all work nicely.

Hi Jim, others,

You could do better with a mercury wetted relay bouncing at 100 Hz
feeding sufficient current to a 50 Ohm load. This use to be the
standard hi-speed circuit for O'Scope calibration in the 60's for the

same range of frequency. If I recall correctly, I used it for testing Sampling plug-ins.

I don't know what I'm talking about - I have not built the
circuit you show on the web site. But I have a number of
thoughts. You may have already considered them - I don't know.
Put diodes across all the relay coils.

Put a diode in the output leg from the pass transistors to
the PWM controller. Yes, it has to be a big sucker > 25 amps.

Consider a redesign: simplify by putting the two transformer
secondaries in series, use a single bridge, filter bank and
regulator. And change the regulator to a LM 317, with a bunch
of 3055's in collector wraparound. Unless you have a compelling
reason against this, give it some real thought. There's a lot
of complexity in your circuit that can be eliminated if you
can use the single LM 317 approach.

I don't recall the mercury-wetted relays being used for high speed step generation -- the earliest devices for that purpose I recall used an avalance transistor, step recovery diode, or tunnel diode. But I do recall the mercury-wetted relay being used as an "input buster", to produce a high speed step at the rated maximum input voltage to a scope input. At the time, it was about the fastest 200 or 500 volt step you could make.

The problem with using a relay or any physically large device for high speed step or noise generation is the inevitable stray inductance and capacitances involved. These will always reduce the bandwidth and flatness of a step. What you have to do is maintain a really clean 50 ohm transmission line environment from the generating device to whatever you're observing it with. And in the case of high speed sampling plug-ins, even a fraction of an inch of the best line you can make will noticeably degrade the signal. When using microwave relays to distribute high speed steps, we avoided reed relays like the plague. They typically use Kovar contacts, because it's magnetic and matches the expansion coefficient of the glass. But the magnetic, relatively lossy material has very bad frequency-dependent skin effect loss, which really trashes a good step.

Brian:

Since there is no need to change from balanced to unbalanced in this situation, you don't really need a "balun".

You might use an impedance transformer, but those are typically used where a broad frequency range needs to be covered.

To match the input or output of a narrow crystal filter to 50 ohms, a simple L network using a coil and capacitor could be used. And by making them adjustable (use a variable cap or coil) you can actually tweak the circuit to optimize performance.

If you go to the index on: http://www.btinternet.com/~g4fgq.regp/ you can find a program called "L Tuner" that will calculate the values for you. There are probably other resources you can use.

Regards,

Roger K6XQ

You canï¿½t do that as the voltage of the transformers are different !!

Best is to either series connect the transformers primaries (watch correct phasing !) and use a full wave bridge rectifier or series connect the dc-outputs of the 2 supply-circuits.
Maximum current is depending on the smaller transformer.
To find out the current rating / wattage you could measure the idling current
of the transformers, the thickness of the wires or the weight of the tranformers.
Probably with the combination of the measurements you will get near that data.

Sure you can do that! The reason it is done that way is precisely
because the two transformer
voltages ARE different. This circuit will allow two transformers with
any voltage differences to
add together.

Draw it out and and mark the phases of each transformer and you will
see that the two voltages
will add together to give the sum of the two transformers.

What you are talking about, putting the primaries in series, will give
half the voltage out. Then
the secondaries are still unmatched. With separate rectifiers for each
transformer it would work
by putting the two dc supplies in series but you would not want to put
the primaries in series.

It is much simpler to do it as I described with one set of rectifiers.
Of course the primaries have
to be phased properly so the output voltages add and not subtract.
(primaries are in parallel)

Hi Roy,

Perhaps this was before your time, or perhaps before my memory
faded....

Anyway, I recall this application, as a standard piece of equipment
from Tektronix explicitly manufactured for the calibration of the
Sampling plug-ins 1S1 and 1S2 for the 545/547 O'Scope (ca. 1955).
Those plug-ins required substantially less than 200-500 volt inputs
(less than 2V actually or it would blow the front end).

The tunnel diodes you speak of (Tektronix (152-0125-00) 4.7ma Tunnel
Diodes) are used in the plug-ins not the calibrator.

The TNS used a different method of noise suppression. It is 100%
different from an ANC 4 or MFJ 1025/1026 device.

The TNS clipped noise spikes based on AGC voltage INSIDE the receiver.
The ANCs keep the noise from getting into the receiver!!

A former TNS user and a proud owner of the ANC 4 and former owner of the
MFJ 1025.

3262. Germanium Diodes

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-04-30 20:42:03 UTC
From: Mark Hall <vze2mhvc@bellatlantic.net>
Message-ID: <3CCF0055.3DE46755@bellatlantic.net>
Source record: 44404

Not too many.. those are germanium signal diodes with a Vforward of about 0.3V.. I believe the 1N90 is also germanium. You might consider schottky diodes which have a Vf of around 0.4 volts, but probably won't work very well as an AM detector. Standard silicon diodes (such as !N4148)have a Vf of 0.6 volts or more. Any Germanium signal diode should have similar characteristics to the 1N34. Not too many around these days, but you might get lucky.

A 5894 socket should also work (ditto for an 832.) Watch for used damaged
GE base transmitter strips that use the 5894 in the final.

I live about 100 meters from 3 sets of 3 phase lines, 66 kv, 88 kv and 105 kv, on the New England Power Grid. I am about 1/4 mile from a substation and 3 miles from a major power generating station on the NE Grid. Potential for lots of line noise and insulator noise.

The MFJ 1025 does not have a preamplifier and was not sensitive enough for my needs. BTW, the 1026 has a preamplifier but I have not used that model.

I picked up the Timewave on eBay for $60 to give it a try. With a small dipole [12 feet] about 1 foot above ground level I can null out S8 power line and insulator noise. This meets my needs. The MFJ 1025 just will not do that at my installation.

Source record: 44410

Hi Guys,

I'm about to embark on my first RX project, 5.80 - 14.0 Mhz AM only . The basic lineup (for a basic RX) is... pre-selector, Variable RF amp, second stage pre-selector, fixed gain RF amp (only if needed) to feed TAK-893 level 17 passive DBM, (LO with high level drive), IF out to tuned IF amp, 455khz (6khz BW) high quality ceramic filter, tuned IF amp, detector, switched capacitor audio filter with notch filter and AF pre and pwr amps.

But I'm thinking of detection now. Is it worth my while trying to implement a simple-ish synchronous detector? Ive heard that this method is well worth the extra effort. Also, Ive read that basically, a tuned limiting amp is used to re-create the carrier, but with detection happening at IF, isnt it just a matter of mixing a carrier at the IF frequency? i.e in my case mixing a carrier of 455khz with a second double balanced mixer to resolve the audio?

Apologies if any of the above sounds amateurish, but thats what I am. And as such, any and all suggestions would be very welcome. Oh, Ive chosen 455khz as the IF, because then my 2 RF preselectors and Local Oscillator can be tuned with a 3 stage variable cap without much of a "tracking" error. Any image problem resulting from the low IF, should have been minimised by the sturdy front-end anyway.

All suggestions welcome....

John.

I've included what I got from reading the explanation of the unmatched
transformer case in an updated schematic at
http://www.ilos.net/~eng/psupply2.gif
Is this what you just tried?

I thought I knew how to determine transformer rated current but since no one else has told you I wonder now if I'm right. My problem was to find a transformer (in my junk box) which could deliver 20+ amps without the AC voltage at it's terminals falling to a level which put my not-so-low drop out regulator out of business. I got four 200W resistors each having a sliding band along the outside to adjust the resistance. I found if I slowly increased the current load and plotted the AC voltage apparent at the terminals I could detect a rather abrupt knee in the curve. I assumed this was where the core was reaching saturation and thus was a bit past the rated current level. Perhaps someone can say if this was an unrelated observation or not.

Jason:

I recall, perhaps incorrectly, that you graduated from an engineering school last year or maybe this year. If that is so, you are sure not giving the school a very good reputation. In my senior year in Physics, we were expected to be able to do exactly what you are asking someone else to do, i. e. draw a block diagram of a system based on the intended application, describe the functionality of each block, and then design a circuit to fit in each block. That was 40 years ago, actually closer to 50. Have college standards dropped that much? All the old profs must be turning over in their graves. :-((

Even with a good pre selector I think that you are going to have image
problems with the 455
kc IF. You could probably get by with it up through about 7 mc or so
but at 14 mc you will
probably have images. I would use double conversion with a higher
first IF. Around 1.5 to 2
mhz should work ok. Or a tunable first IF and a crystal controlled
first mixer.

On the synchronous detector it sounds like you have it about right. It
works like a product
detector for ssb but the trick is that the inserted carrier has to be
exactly in phase with the
received signal carrier. That can be derived in a few different ways
from using a phase lock loop
on the received signal to running a sample of the received signal into
a limiter or using the two
side bands of the am signal to make a carrier to feed to the product
detector. Each has it's
problems. I would get it going with a regular diode detector first
then play with the synchronous
detector.

If you have an ARRL handbook, in the power supply section they tell
you how to roughly
determine the power ratting of a transformer by the cross section size
of the core.

If you can measure the wire size of the secondary wire on the
transformer you can also look in
the handbook on wire size in transformers and it will give the current
ratting when used in a
transformer. The problem is though that most of the time the wire
comes out with a pigtail of
stranded wire that is not what the transformer is wound with. So the
best bet is probably trying
to determine from core size. I used to know the approximate figures
but can't remember.

I take it that you are just using 2 diodes in a full wave circuit with
the two transformers and not a
bridge circuit like that of the drawing that the other poster shows.

Mike,

You don't want to ground the center tap on the transformer and use a bridge rectifier at the
same time. You will have a dead short! Either use the bridge rectifier and no center tap or use a
full wave rectifier (2 diodes) and the center tap. By the way 2 of your diodes are backwards in
the bridge.

In the second diagram of the two transformers that are not alike, use just a full wave rectifier (2
diodes). Get rid of d1 and d2 and the ground on them. Use your d3 and d4 only. But they are
backwards also. You would have a positive ground supply the way they are shown.

> Gary K4FMX

Yes I am useing just the 2 diodes in a full wave circuit. The center tap of one transformer is negative and the centertap on the other transformer is positive. Another thing I did this afternoon was take some BIG hi wattage resistors and put them across the outputs of the transformers (centertaps) with an ammeter.I just kepted reduceing the resistance untell I saw a voltage drop. I was able to see just over 800Ma befor seeing any voltage drop at all. About 1500 volts.

What I'm hopeing to use this power supply for is a plate supply for 2X4cx250.

4CX250s do not perform well at 1500V. They improve remarkably at 2000V, in terms of both power output and linearity. Aim for an absolute minimum of 1800V at full load - anything less will be a disappointment, and a waste of your time.

==========
If a transformer is well designed , eg iron and windings (diameter) match ,
the current rating can be found by loading the transformer until de output
voltage has dropped by 5 percent. This is a practical way ,be it NOT
scientific . For a HV transformer the load can be made from high power
resistors or a number of 120 or 230 V lamps in series . Especially the
latter method requires ample safety consciousness.
A Variac (variable auto-transformer) in the 230/117 V primary circuit will
be very useful while performing the test.

Curiously enough, I've been working on a similar project for a few weeks, but double conversion. Right now, I've got the AF amplifier, detector, AGC amp and one 455 KHz IF stage built and working, so I've got a long way to go.

I decided to start with a simple 455 KHz envelope detector, with the plan to build in a modular fashion so that I could add synchronous detector after the rest of the receiver is working.

After trying three different envelope detectors, I found the best performance, in terms of THD, with what Walter Jung's Op Amp Cookbook describes as a "semi-precision rectifier" using a TL074 quad op amp and 1N270 rectifiers. I also take a feed off this detector for my AGC bus. I measured the THD as 0.6% with this circuit, for a 1000 Hz modulating tone at 95% modulation. That's the limit of my signal generator, so the detector may actually be better.

The circuit is shown in recent ARRL handbooks, Figure 17.31 in the 2000 edition shows it used purely as an AGC detector. Searching around the internet for "precision rectifier op amp," I found the underlying circuit in many places, such as Figure 8.3 in newton.ex.ac.uk/teaching/CDHW/Electronics2/PHY2003-08.pdf

I first used 1N914 silicon diodes, as usually recommended, and found that I couldn't get the distortion below 3% or so. Switched to germanium 1N270 diodes and saw the THD drop to around 0.6%.

If you are interested, I'll e-mail you a copy of the schematic. Drop me an e-mail if you want it.

If the noise saturates or overloads the detector, audio processing is often too late in the receiver chain to fix noise. There is nothing to recover if there is not any signal left after the detector. It all depends on what is going on at the detector stage.

Remember all those impulse noise reduction circuits that detected an impulse and reduced the RF/IF gain for the duration of the impulse? They worked pretty good, didn't they?

[Why does pressing the noise reduction button on a TS50S work a lot better than pressing the same button on a commercial marine ICOM M710 SSB?]

One can download for free a audio filtering app complete with source code for the Analog Devices 21xx DSP dev kit that does a lot of reasonable DSP audio things.

The phases are adding correctly, but what about the current ?
I understand that the current of one transformer is also flowing
through the opposite winding and so probably reduce the
allowable current to a lower value then using the transformer alone ?

>What you are talking about, putting the primaries in series, will give
>half the voltage out. Then

Right, I was thinking of course of putting the secondaries in series..
with the primaries in parallel
and use then a full-wave bridge rectifier (4 diodes)
giving me about 3450 Volts idling voltage at the smoothing capacitor.

In the past I was using a HF-amplifier with 3 x 4CX350F at 4KV
anodevoltage very succesfully.
4KV was noload, 3,4KV at full output
With voltages at less then 2500V they draw grid-current very quickly
and efficiency was not as high as expected...

>Peter, DF3KV

Yes Peter, the total current will flow through both transformers but
the current will be no
different than if the transformers are in series. In series the total
current also flows through both
transformers. These transformers are effectivly in series when the
diode conducts so the same
current flows through both.

Your methode of hooking the secondaries in series and using a bridge
rectifier is fine also. But
with a bridge you get twice the voltage that you do with a full wave
circuit. sometimes a bridge
may give too much voltage with the two transformers in series. This is
just another way to use
two oddball transformers together.

Remember that when you use a bridge rectifier you must cut the current
ratting of the
transformer in half from what it is with a full wave rectifier. There
is only so much power that
you can get out of a transformer. When you double the voltage, with a
bridge, that leaves you
with half the current capability to equal the same power.

With two transformers you get the benifit of the total power
capability of both transformers
added together. By the different rectifier connections it gives you
more choices of voltage
outputs. Either way you end up with the total power capacity of the

two transformers.
As long as you don't exceed the current ratting of either
transformer.

Message-ID: <3CD01814.EBD35E47@neicoltech.org>
Source record: 44431

Hi gang,
My son and I are building an SSB exciter that we want to put on 2 meters. I am looking for a DDS VFO to use as an LO for a mixer to get up to 144MHz.

The exciter is still being designed so I don't yet know what range of LO I might need, but lets say for now that I after something that will do approx. 3~50MHz with reasonably low phase noise and 10Hz steps. A unit in kit form would be prefered. Any suggestions?

Thanks
Bob L. WB0POQ

3292. Source for RTL chips?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-01 16:54:38 UTC
From: Roger Leone <arleone@inreach.com>
Message-ID: <M5Vz8.1095$bZ2.147540001@news.inreach.com>
Source record: 44434

Thanks for reading my post.

In 1972 I built a Micro-TO keyer from that year's ARRL Radio Amateur's Handbook (it originally appeared in Aug 67 QST). It worked fine for many years, but when I fired it up a few days ago it was dead. Turns out that one of the RTL chips (Fairchild uL914) had failed. With it out of the circuit, the rest of the keyer (pulse generator, flip-flops) works OK.

I have searched the current replacement semiconductor distributors, none of which even list this component or any of its variants (Motorola MC814G or HEP584), let alone have a replacement in stock.

Does anyone know where I might find one of these?

I am considering replacing it with a chip from another logic family, but that involves making up an adapter board. I could even use discrete transistors or a transistor array, since the original chip was pretty simple inside. But I'd prefer using the correct chip if possible.

Thanks and 73,

Roger K6XQ

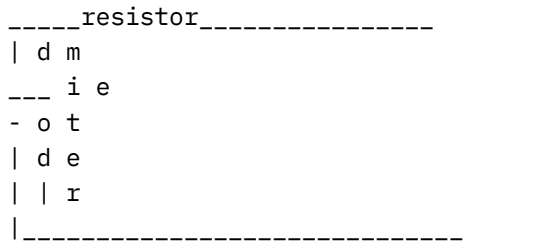
news:<Ekzz8.83$qP1.5712@bgtnsc04-news.ops.worldnet.att.net>...
> What diodes are similar to the 1N34A?
>
>
An important thing to remember is that most of the time when a "1N34" or
"1N34A" is specified, someone is in fact calling for a generic, small
signal germanium diode. The germanium being the key consideration here.

So when you see a "1N34A" specified somewhere, what you want is a small
signal germanium diode. These haven't been commonly used in decades,
silicon diodes taking over the work in most cases. The exception is
when you need the low voltage drop of germanium, like when building
a "crystal radio".

So when you ask for similar diodes, you are really asking the wrong
question. Because if a "1N34A" is hard to come by, finding some other
germanium diode would also be difficult to find. If you find a place
selling germanium diodes, considering the years of specifying a "1N34A"
when germanium is needed, either they will stock the actual 1N34A or
use it to denote a germanium diode.

If you can find old enough equipment, then you may find germanium diodes.
it doesn't really matter about the part number. When this has come up
before, someone mentioned finding germanium diodes in recent "transistor
radios" as the detector diode. I've never checked this, so I can't
confirm. You will be able to differentiate germanium from silicon,
because the former will have a lower reading when using a "diode test"
function on a DVM. If you don't have such a function, set up a test
jig with a 9volt battery, a current limited resistor and some sort
of voltmeter.



The meter will show the voltage drop across the diode.
Silicon diodes will show a higher reading than a germanium.

Michael

Fine Gary,

I totally agree with your explanation.
But following has to be remarked:
In a centre-tap configuration with fullwave rectification the maximum
permissible current to be drawn is twice as high as the winding is layed out
for.
Current flow is 50% / cycle through each winding half.
For example the transformer has a centre-tapped winding 1000V 0,5A
this transformer has got 500VA, so you may draw 1A at 500V CCS.

With fullwave bridge rectification the current maximum is 500mA at 1KV,
current flow through each cycle is 100%.

Message-ID: <aap8p7sfc1@knossos.btinternet.com>
Source record: 44437

For a 9:1 impedance transformer, at 9 MHz, use an HF-grade ferrite ring about 1/2-inch in diameter. Wind on 24 or 27 turns of fine-gauge enamell-insulated wire. Tap the winding at 1/3 (8 or 9 turns) of the total number of turns.

For a lower frequency transformer like 455 kHz use 4 or 5 times the total number of turns.

For a 4:1 impedance ratio tap at 1/2 of the total number of turns. Its so simple you can't believe it.

Agreed Peter.

You have to be careful of how transformers are ratted. Most
transformers with a center tap the
given current ratings are for a full wave circuit. Using that same
transformer with a bridge you
have to de rate the current to half. Transformers without a center
tap may have their current
ratting with a bridge rectifier. The transformer spec sheet will
usually specify.

Roger,

RTL??? Haven't even heard of that in over 20 years ... been
out of production longer than that ... didn't have a very long
production life, either as I recall, so probably not much around,
even in junk boxes.

Let's see ... you built the keyer in 1972 from a 1967 design ...
that sounds like the RTL parts were probably obsoleted by
early TTL at the time you built it ... sounds to me like you
got your money's worth out of it, though :-)

I know it's heresy, but have you considered just getting one of
the single-chip keyer chips and making life easy on yourself?
(Besides, it'll run from something like a 9V battery for a LONG
time ...) If it makes you feel better, you can probably re-use
the case so it looks like the old familiar unit :-)

I assume you are chose a 455KHz IF because you have a filter for
that frequency. Because filter availability aside, I think it would
be easier to have a higher IF. You talk about tracking, but you
can do away with that alignment by having a preselector control separate
from the VFO. If you have a high enough IF, it's easy to peak on
the right image, but with a 455Khz IF, a separate preselector control
would be troublesome. If you can't go with a higher IF, I'd add
my vote for double conversion. There are a number of consumer items
that you could pick up at a garage sale (or church or scholl rummage sale)
that would have a rather wide 10.7MHz ceramic filter, a crystal
to convert to 455KHz, and a 455KHz FM-bandwidth filter for that matter.
Portable phones, 49Mhz superhet walkie talkies, maybe some cellphones,
and CB sets will often offer up these components (there are exceptions,
because you do see portable phones that do a single conversion to 455KHz,

as will some of those walkie talkies and CB sets).

As for a fancy detector, I'd go with the other suggestion, of starting with a simple diode detector to get it going, and then a plug-in detector to try various things.

There is plenty to play with in the form of a "better AM detector" and whether or not they really improve things (in rec.radio.shortwave there is varying opinions on the subject), trying different schemes may be more interesting than building the basic receiver.

There are a bunch of different schemes that would be referred to as "synchronous detectors" some of which probably aren't. The basic scheme is to use a a strong locally generated carrier or regenerated carrier to beat the incoming signal down to audio. The need for the "synchronous" part is so there isn't a beat with the incoming signal, and more importantly, so the inserted carrier is exactly in the middle between the two sidebands.

(Of course, you can avoid the need for matching the reinserted carrier to the incoming signal by using a sideband-bandwidth filter, and using it to convert the incoming AM signal to an SSB signal with suppressed carrier, at which point the product detector converts it to audio just like any other sideband signal.)

One of the earliest schemes is simply to boost the incoming carrier in reference to the incoming sidebands. This is one of the early uses for the Q-mulitplier. It had a nice narrow peak, but lousy skirts. So by setting it right, you'd boost the incoming carrier enough.

Al the rest of the schemes use an outright product detector.

Sometime in the fifties, someone wrote an article in QST for a fancy receiver. It featured two IF strips. One was an AM-bandwidth channel, for normal AM reception. The other was a CW-bandwidth channel, obviously for CW, with a product detector and BFO. But if the usual diode detector wasn't good enough, you could put the product detector at the output of the AM channel, but instead of the BFO feeding the detector's other input, the output of the CW channel would provide a regenerated carrier to beat the incoming AM signal to audio.

More recently, you'd see circuits that were similar. But instead of a narrow filter to extract the incoming carrier, there'd be a limiter to take out the amplitude variations of the incoming signal, and that would beat in a product detector with the incoming signal. Sometimes you don't even need a specific limiter; an early article on the MC1496 double balanced mixer said that you could use the lower transistors as a limiter, so long as the signal was strong enough.

Motorola made an IC, the MC1330P, to do this. Those may be hard to come by, though I've found them in a TV set or two.

The most useful solution for this would now would be some sort of
FM IF strip. Some of them use a FM detector that is a balanced mixer,
and you just don't put in the phase-shifting circuitry that you'd
need for FM.

The ones with limiters have been called "quasi-synchronous". If the
signal gets too weak, they may stop working. And none of the above schemes
work for DSB with no carrier, since they count on an incoming carrier,
however weak, to extract.

The simplest synchronous detector would be a phase-locked loop, and
a product detector.

And then of course, you can get fancy and have selectable sideband
in the synchronous detector, via phasing techniques.

I've glossed over the ones where the incoming signal is doubled,
and then divided by two, to provide your locally generated signal.
This works without any incoming carrier, because it's working
on the two sidebands.

This is very true! But it is true for most parts we use, like
transistors, you need only a smaller amount of types, but still it is
lot of cries for different types we really don't need for success with
our constructions

�L914, according to my 1969 Motorola Semiconductor Data Book is a
dual 2-input NAND/NOR-gates. A good replacement is usually made from a
BC238 or similar NPN-transistor with few resistors and/or diodes per
gate. I have some experience simplifying the amount of gates -
particularly with CMOS which I have used since 1974.

The list says "NAND/NOR-gates", but the symbol on next page shows
NOR-gates

Bob
John Miles and I have been working on a board that could fit your
requirements
You can see phase noise plots at http://www.qsl.net/ke5fx/synth.html
of an earlier version running at 1 GHz. This uses a filtered DDS covering a
narrow range for fine resolution as the reference for a PLL and VCO at
signal frequency
The board should accomodate VCO modules (Minicircuits ROS series) to cover
50 MHz to 2.5 GHz or so and the National PLL chips to cover a similar range.
Parts are virtually all surface mount
It is a matter of changing software, loop filter and regulator voltages to
fit your choice of components. It is not available in a kit but parts are
available from a limited number of suppliers.
I am ordering the second proto board run *today*

As my understanding, the kit is already discontinue (Epiphyte 2).
The simple SSB transceiver ever seen is a valuable one.
Still the Far Circuit is handling the epiphyte board of previous version.
But I suppose a few parts used in the Epyphite are few to find in market.
Especially MURATA 455Khz SSB ceramic filter is difficult to obatain
even in Japan.

I hope you will find un-assembled kit in the QRP-L FS, or the next
transceiver which will be released from SWL is your another
choise to get nice 80m SSB transceiver.

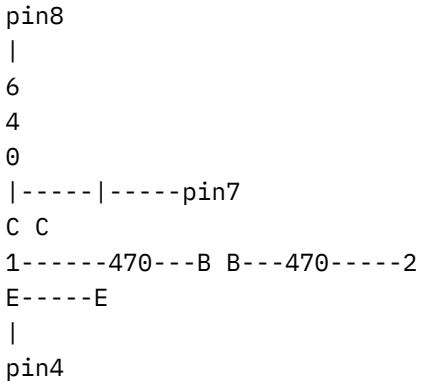
One time when this came up before, Don Lancaster swooped in to mention
some companies that deal in obsolete semiconductors. I think he caught
the post because I mentioned his "RTL Cookbook".

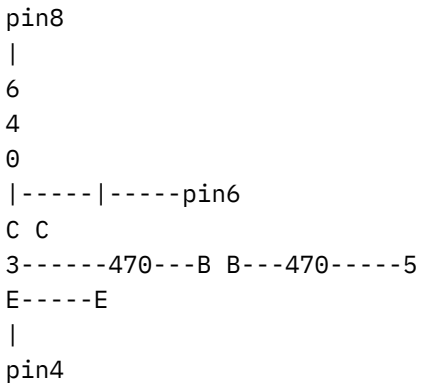
There really isn't much to RTL, and luckily you need a gate, not a
flip-flop. Thirty years ago, you could find articles that would tell
you that you could just as easily build up the gates with discrete
components. I can picture someone saying to use 2N706s. The RTL
Cookbook does show resistor values, but at a glance I don't see
the reference to 2N706.

In this particular case, you only need 3 npn silicon transistors,
3 470 ohm resistors, and 2 640ohm resistors. The flip-flops were
worth doing by IC, but that 914 could have just easily been done
with discrete components.

I think building up the circuit is legitimate, assuming you want
to keep the circuit "authentic". If I looked enough, I could find
the article or two where the author built up their own RTL equivalents
with discrete components.

I suspect if you start trying to replace any of the ICs with other logic families, you'll have to replace all of the ICs. Not costly, but once you move away from RTL, the circuit, particularly that diode from the paddle to the 914, may need reworking.





I hope that makes sense.

Thank to all who replied, here or direct...

Several sources of these old chips have been suggested and this has stopped my plans to substitute another logic family or create gates from discrete components.

I was sort of looking forward to some experimenting, but it is no longer necessary.

Regards,

Roger

A conventional envelope detector (using a single diode) definitely needs an IF amplifier with a bandwidth comparable to the transmitted bandwidth. If a large spectrum enters into an envelope detector, there will be all kind of beat frequencies between unwanted carriers and unwanted sidebands falling into the audio passband.

However, if a true synchronous product detector is used, the only beats occur between the locally regenerated carrier and the incoming spectrum. The beats between the local carrier and unwanted carriers and their unwanted sidebands will fall on high audio frequencies, which can then be removed by an audio filter after the detector. Thus, quite wide IF filters could be used, so a single conversion with 10.7 MHz IF might be possible. Other convenient IF frequencies, with lot of filters available, would be the TV-audio subcarriers at 4.5, 5.5, 6.0 or 6.5 MHz depending on the region. The width of the IF filters control the total amount of power entering the product detector, thus, controlling the available dynamic range.

The old (1974) Signetics data book had an application note about using the 561 PLL (which also contained an additional product detector for AM demodulation) as a medium wave (550-1600 kHz) receiver without a single LC circuit. Apparently the dynamic range would be very poor with the whole spectrum entering the product detector. However, with a good preselector a direct conversion synchronous AM detection would be quite possible. Unfortunately it has always been hard to find these obsolete chips.

Hi John,
many years ago I played with AM synchronous detectors, namely with one based on TAA661 (absolutely obsolete now ;-) The carrier was regenerated by limitation of the AM signal and then mixed with the original signal - both at IF 455 kHz. When I replaced a common one-diode detector with this circuit, many weak signals appeared on the band. I saw no effect on strong signals. So, both in theory and in practice, the product detector drastically improves the reception of weak AM signals.

It's not really a "noise canceller" as it is what MW and SW DX'ers call a simple phasing box. It's job is to create two signals 180 degrees out of phase and sum them to produce a null. In other words, it cancels whatever arriving signal is made to be 180 degrees out of phase in the two antenna inputs. In the case of the MFJ, one input is supposed to be a short whip or similar whose job it is to pick up the local noise source while the other input is the main antenna. I don't know how they do the phase adjustment works (could be L-C, could be delay lines, could be a one of several other ways) but the fundamental idea is the same.

It is not considered a robust front end in the MW DX'ing community. Mixing products have been noted by a lot of people. If you want to roll your own, I'd look at other designs. Go to http://www.qsl.net/wa1ion/ and you'll find his web pages of presdelectors and phasing units. One of them will surely do the job for you.

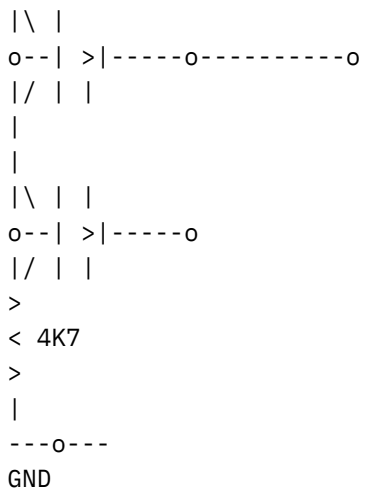
In most cases I find you need even less. Many of my projects used discrete components for the gates, particularly in the early days when funds were severely limited and I had to make do with whatever parts I could find.

Here's the OR gate, just two diodes and a resistor:



Reverse the diodes and connect the resistor to VCC for an AND gate. Of course, there is no buffering so you can't cascade these types of gates, but most often they are fine for driving TTL inputs, e.g. say you have a 74LS393 dual 4-bit binary counter and you are making a clock, you want to decode the 10 count and cause a reset, to get proper counting from 0-9. Using this kind of AND gate (on the Q0 and Q2 outputs) to feed the reset input works just fine. Adding a single transistor stage buffers the output if you need it, and creates a NOR (or NAND) gate.

I did this many times, it works well and is often worthwhile even if you do have the needed TTL chip. E.g., if you only want one AND gate, you don't need to use a whole 74LS08.

I want to build a two-tone oscillator for testing linear amps. I was thinking about using 555's for the two frequencies. But they seem to be poor sign waves generators and so would need to either build a low pass filter or make discrete oscillators. Does anyone have any experience in building one of these little animals. Any resources for drawings? What about frequencies?.. I would suspect they shouldn't be harmonically related?

For a clean AF sinewave oscillator, I like the "twin T" (aka phase shift). It can be built with a single 2N2222, and makes a very nice waveform. You would need 2 circuits connected through a couple of resistors to combine the outputs. You should be able to find a skez in any ARRL Handbook.

Radio Shack sells some relatively inexpensive data link modules
through the web. They are about $10 US for each receiver or
transmitter. I believe they operate in that 300 MHz band where
remote controls, etc operate.

If you want specifics and can't find them at www.radioshack.com,

Do you want to test RF amplifiers?
If so I presume you would apply two tone audio to your SSB generator in this case. The problem with this is that any incompletely suppressed carrier and opposite sideband may interfere with the test and not reflect the true IMD performance of the amplifier. An alternative approach would be to use two RF oscillators and combine them in a hybrid befoire applying them to the amplifier.

A two-tone test oscillator is the easiest means to conduct the tests.
I have one I built from an old Radio Handbook (not ARRL) that uses an
LM324. You need a low distortion oscillator and a 555 is not it. Try
a search on the Internet. You may even find a kit available.

Source record: 44377

The search engine radio-portal
http://www.radio-portal.org
was restructured completely. Now the following search options are at
your disposal on the start page:

Detail Search:
Here you may enter several search terms, which can be combined by the
operators
exact / and / or.
These functions offer the opportunity to adopt the selectivity of a
search. This is a great improvement compared to the previously used
routine. Now your search phrase does not have to fit exactly the
text in the database to get a usable result.
Additionally, a search can be restricted to one of the 63 categories.

Category Search:
These option corresponds to the former "Search in broad". Here you can
combine two of the given categories by the operators
and / or / not.
For example 'Reviews' and 'Antennas', to get an impression on choosing
one's own equipment.
This search routine is extremely useful to get an overview on a field of
interest - a search phrase is not necessary.

Advanced Search:
On a separate page all functions mentioned above can be combined at the
same time. So it is possible to restrict the number of results to a
senseful value or to find entries belonging to various search phrases or
categories.

I am currently working to enable a search within results pages as a
further option.

You will find further explanations and operating examples via the "FAQ"
Button.

The Classified Advert pages have been updated also. Here you can offer
or search for hobby related items.

I hope you will like the new options. They are meant as a help to find a
quicker way to radio related information. Meanwhile more than 34.000
pages are in the database - all of them were checked manually. Probably
one of the reasons, radio-portal got the Millenium Innovation Award by
Radio Netherlands Media Network in the year 2000.

Your comments will be appreciated.

Regards, have a good weekend.
Willi Passmann, DJ6JZ

3336. FA: Vacuum Tube Textbooks

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-03 13:50:47 UTC
From: zoxx@my-deja.com
Message-ID: <aau4jn$5m8$1@news.netmar.com>

For Auction - Three hard-to-find classic textbooks on vacuum tube
circuit design:

-Theory Of Thermionic Vacuum Tubes, E.L. Chaffee, 1933
-Electron Tube Circuits, S. Seely, 1950
-Fundamentals Of Vacuum Tube Technology, A.V. Eastman, 1941

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=1727595321

This comprehensive reference library is a must-have.
Reaonable minimum bid with no reserve. Aution ends May 5th.

>>I also have several lots of NOS tubes for auction; (4)6JE6C, (2) 6KD6,
and (22) 837/VT-101.

..My sincere apologies if this posting is inappropriate for this group.
Thanks for looking...

3337. QRP SSB 80/20

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-03 13:52:43 UTC
From: Itsme <antwoord_mij@hotmail.com>
Message-ID: <3cd2962b$0$8168$ba620e4c@news.skynet.be>
Source record: 44378

Hello,

I'm planning to build a small QRP SSB TRX for 80 and/or 20.
Where can I find exemples? I've grownup with valves so don't know much about calculating transistor setups.

All info is wellcome - thanks in advance de Jos (ON7JQ)

> A two-tone test oscillator is the easiest means to conduct the tests.
> I have one I built from an old Radio Handbook (not ARRL) that uses an
> LM324. You need a low distortion oscillator and a 555 is not it. Try
> a search on the Internet. You may even find a kit available.
==========
In ARRL Handbook 1986 ,page 25.27 you can find a 2 tone generator (700 -
1900 Hz) with 3 double J-FET Opamps , LF-353N running on two 6v batteries
.
Complete with Hi&Lo Z output and 0,-10,-20,-30,-40,-50 dB attenuator .

In ARRL Handbook 1995 , page 26.38 you can find a hybrid combiner for signal
generators (for 2 ranges : 1-50 MHz and 50 - 500 MHz) for 2 tone testing by
applying RF ,as per Richard Hosking' suggestion.
To test a (linear) power amplifier one would need to add an intermediate
amplifier.

Hey, I got this very large variable cap out of a ham transmitter, I've never actually seen one this big in person, it was out of a 10 meter ham transmitter, The engraving says Barker and Williamson
Type CX 49 A
Does anyone have the tech specs on this or how much it would be worth?
Thanks
Azoth

Murphys law at work. I bet you have the 1992 and the
1994 Handbook. There is a circuit for a two-tone
oscillator on page 25-22 of the 1993 ARRL Handbook.

Frank,
Yup, you're right. They removed it in the newer handbooks that I have (2001-2002) But it's in the 86 to at least the 91 version. I didn't look in the older handbooks, figuring they wouldn't drop something like that. But..<shrug>.. Anyway, this is perfect. Just what I'm looking for. Thanks to everyone, and I feel a little sheepish for not looking in 'all' the versions of the handbook.

From: Henry Kolesnik <wd5jfr@oklahoma.net>
Message-ID: <ud64k3o372hq55@corp.supernews.com>
Source record: 44386

Received field strength is reported as so many microvolts per meter. I recall reading an old article that shows measuring this value using a loop antenna with a calibrated signal generator in line. The loop is oriented for maximum reading on the receiver S meter which is recorded. Next the loop is oriented for minimum reading and the signal generator adjusted for the same S meter reading. The questions are how is the signal gen inserted so the impedance isn't distrubed and how does one determine the length in a loop? Any ideas or direction to good practical info appreciated.
tnx

3345. "Natural Radio" VLF Discussion Group

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-03 23:20:42 UTC
From: korgans@aol.com
Message-ID: <20020503192042.04365.00006587@mb-bh.aol.com>
Source record: 44387

This is an announcement concerning an e-mail based "natural radio" VLF discussion group. This group contains members from all walks of life who are interested in discussing "natural radio" and related topics to "natural radio" VLF monitoring. VLF listeners now have an outlet for discussing "natural radio" related issues and similar topics in a group format. Current VLF activity, whistlers, chorus, schematics, receiver designs, etc., are all welcome.

The natural radio VLF group is a discussion group dedicated to those who enjoy monitoring radio frequencies in the VLF radio spectrum and slightly below the VLF spectrum (3-30 KHz). We listen to the amazing "radio" sounds created by planet earth such as whistlers, chorus, tweeks, risers and hiss on simple VLF receivers. Listen to beautiful bird like sounds created by the northern lights while watching them at the same time! Listen to an oncoming solar flare impact our planet's ionosphere and magnetosphere live! Listen to distant lightning ring during nighttime hours. Study sprites and jets! Discuss VLF receiver designs. The sky is the limit when it comes to VLF!

To join the VLF discussion group simply send a blank e-mail to VLF_Group-subscribe@yahoogroups.com. Once subscribed, all messages sent to VLF_Group@yahoogroups.com will be sent to all members who are part of the VLF discussion group. The VLF group is an e-mail reflector and is a recent endeavor to try to tie VLF listeners together by e-mail for discussion and alert purposes. Feel free to subscribe or unsubscribe from this group at any time. You will be sent a confirmation e-mail and further information upon successfully subscribing to the list.

For further information check the VLF group web site:
http://groups.yahoo.com/group/VLF_Group/

Amp Supply Co. LA-1000 HF Amp. 160-10m

Have for sale or trade an Amp Supply Co. LA-1000 HF amplifier. Late 80's model, with Ameritron serial placard. Manual states 500-600w output. Tubes are doing about 450 on 80m. Amp is in good shape and working perfectly but has a few scratches. Power switch has been replaced with incorrect but heavy-duty switch. Looking to sell or trade for a Dualband mobile such as TMV-7A or similar. Will only consider Icom, Kenwood and Yaesu mobile ham radios depending on mod availability. Will also consider only Motorola/Radius handhelds or mobiles (Max, GM, M1225, etc, as well. Jedi, Radius or Pro series.) Prefer VHF. U-ship, (will average $20-$35 CONUS).
Thanks and please reply direct,
Randy, KC8CPK

3348. FS: Old Radio Books, 1920's - 40's

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-04 03:11:07 UTC
From: oldbooks78@aol.com
Message-ID: <20020503231107.11923.00007557@mb-mk.aol.com>
Source record: 44390

I currently have the following old radio books available. Media Mail postage is $3 for the first book and $1 for each additional item. The books are:

Rider, John F. The Cathode-Ray Tube at Work published by Rider Publishing, 1944. The 336 page hardbound book is in very good condition, clean with no page tears or pen marks except for a brief gift inscription inside the front cover. Dust jacket is in about very good condition. An early thorough treatment of cathode-ray tubes and their applications. Chapter titles include THE THEORY OF THE TUBE / SWEEP CIRCUITS / VOLTAGES ON BOTH SETS OF PLATES / COMMERCIAL CATHODE-RAY OSCILLOGRAPHS / PRACTICAL APPLICATION OF THE CATHODE-RAY OSCILLOGRAPH / ALIGNMENT OF TUNED CIRCUITS / THE A-F FREQUENCY MODULATOR / AUTO RADIO VIBRATOR TESTING / TRANSMITTER ADJUSTMENT / OTHER APPLICATIONS. A nice item. Available for $10.

Lauer, Henri and Harry L. Brown Radio Engineering Principles published by McGraw-Hill, 1920. First edition, second impression. The 300 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Very clean cloth covers with gold lettering on the spine, very bright. A nice early text on the radio, with many great photos/illustrations. Includes a section on early aviation radio. Available for $18.

Measurements Development Laboratory of the Sperry Gyroscope Company Microwave Transmission Design Data published by Sperry Gyroscope Company, 1944. Publication No. 23-80. The 215 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Originally issued during WWII as a "confidential" document. Chapter topics include General formulae for concentric lines; Attenuation in concentric lines; Reflections and impedance matching; General formulae for wave guides; Attenuation in wave guides; Reflections and impedance matching in wave guides; Wave guide tees and bends; Wave guides filled with dielectric material; Dielectric material: Cavity resonators; and Measurement techniques. A neat early book on ultra-high frequency radio waves. Available for $10.

Everitt, William Littell Communication Engineering published by McGraw-Hill, 1937. Second edition, fourth impression. The 727 page hardbound book is in very good condition, clean inside and out, with a sturdy binding. A nice early radio engineering text. Available for $10.

Nilson, Arthur R. and J. L. Hornung Practical Radio Communication: Principles, Systems, Equipment, Operation Including Short-Wave and Untra-Short-Wave Radio published by McGraw-Hill, 1935. First Edition, fifteenth impression. The 758 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Blue leather-like covers. Overall, a particularly nice copy of this early radio text. Available for $15.

Rider, John F. FM, An Introduction to Frequency Modulation published by Rider Publishing, 1946. The 142 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. A nice early look at frequency modulation. Available for $9.

Markus, John and Vin Zeluff (editors) Electronics for Engineers; Reference Articles, Charts, and Graphs from Electronics Magazine published by McGraw-Hill, 1945. The 390 page hardbound book is in fine condition, fresh and clean inside and out. Original brown paper cover with sticker title labels in near fine condition. First edition, fifth impression. The book is a collection of radio communication, radio broadcasting, television and radar design articles that have appeared in Electronics Magazine from 1939-1944. An excellent copy, about as nice as one might find anywhere. Available for $14.

ARRL The Radio Amateur's Handbook, 32nd Edition, 1955 published by the American Radio Relay League, 1955. The 600+ page softbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Some wear at the base of the spine, with a small 3/8 inch tear along the lower front spine edge, but not bad at all. Overall a very nice copy of this early ARRL handbook. Available for $10.

Rider, John F. And Seymour D. Uslan FM Transmission and Reception published by John F. Rider Publisher, 1948. No Jacket. First Printing. The 409 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. Covers the basic principles underlying the operation of FM transmitters and receivers. Available for $8.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Best regards.

Dave

3349. Monster Variable Capacitor!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-04 13:29:23 UTC

You should be able to get some idea of the value by looking at similar caps. R.F. Parts has a reasonable selection of transmitting caps.

Variable caps are pretty simple ... you could measure the capacitance with a cap meter. If you don't have access to a cap meter you could build up a bridge including the cap, excite it with RF, and with the help of an RF voltmeter and a little math you can figure it out, too. At worst, you could measure the size of the plates and a little math will get you close. Similarly, the voltage rating is nothing more than another way of measuring the plate spacing.

B&W was a pretty common provider of transmitting caps a while back so perhaps a browse through some old copies of the ARRL handbook might come up with some specs, too.

I don't recall the model number but I once had a military surplus direction finder receiver that had a cap similar to that in it. It was made by Bendix. The whole unit was probably 12X12X14 or 16 and was gear driven from a remote similar to that of the old BC/command series.

Above is very likely , as you need loading capacitor values
between 100 and 4000 pf depending on impedance and band.
Gangs will be switched (added) for lower frequencies.

3357. Repair of Bird Elements

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-04 18:26:40 UTC
From: J Koli <jkolin@optonline.net>
Message-ID: <AJVA8.130024$sl3.29673593@news02.optonline.net>
Source record: 44299

Anyone have experience with repairing Bird Wattmeter elements that can advise on parts list and diagrams?

I opened a bad 50H and find a burned component and a glass diode. Can't figure out what that burned components is. And...someone said they normally don't come with a glass diode.

Thanks....Jay NE2Q

Ones that size are not at all unusual in some of the multi-stage TRF
sets.

Sounds like about the same total capacitance as the 4-gang 600pF one I
have...but I _know_ what that was used in. (Maybe I'll use mine to
tune an LF loop sometime...)

One fun thing you can do with it, if its insulation is good enough to
hold a charge for a few seconds, is to set it to max capacitance and
charge it to, say, 200V. Disconnect the charging voltage, and open
the plates (turn toward less capacitance). Watch/listen for sparks.

Cheers,
Tom

I had one from a BC=??? TRF rx . The unit had a plug in coil set that went into the side of the box. T he tubes if I remember were of the double digit type. The rx was new when I bought it in 64 and made if I remember correctly by Emerson?? Never could get the darn thing to work as there was a myriad of connections and a control box between the rx-tx. 73 Tom KI3R

Doug, you should not have much trouble rebuilding the PTO.
Check with the Ten-Tec reflector at http://www.contesting.com
if you get into troubles. T-T sells a repair kit and you can visit
with
the techs when you order it.

Hi Andre,
Try this from the UKSMG web site; not quite 500w as it is billed as a
450 watt pa, but it seems to fit your needs in all other respects.

3370. 7 mhz qrp amp 'brick' needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-05 13:25:48 UTC
From: hexter@blazenet.net
Message-ID: <udacmsa8flj689@corp.supernews.com>
Source record: 44312

I have built a very nice AM modulated 7 mhz qrp rig with nice audio characteristics (115% forward / 100% negative) and it's output is 10vpp carrier, 22vpp peak modulation, at 500 ohms. I run it through a ferrite balun for 50 ohm antenna match. I am looking for an integrated circuit 'brick' to give me 5 watts of carrier, with 25 watts of reserve for peak modulation passage. Supply voltage can be anything, I will build the supply. I am guessing I need a 25 watt brick with perhaps 30db gain. Anzac perhaps? Any ideas (under $100)

3371. ft7100 Mic and PTT help. Please!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-05 20:43:06 UTC
From: "AcKBaR[KAC]" <>
Message-ID: <8a6bdugonuq2e59v7ts8v9fv7mq7brno0r@4ax.com>
Source record: 44313

I am trying to wire up a ft7100 to one of my motorcycles like I have my IC 706 on another.

The only problem I am having is how to wire in a mic element and a PTT to the jack on the side of the head. When I touch PTT to ground, it does not key the radio. I can key the radio by grounding the PTT pin on the data jack, but I do not think that allows audio.

I want to ad a simple radio shack mic element for testing till I get to Dayton to buy a Heil.

Any suggetions?

I'm pretty sure that each of them has a diode and a resistor. The
diode is the detector for the meter, and the resistor, together with
the size and shape of the pickup loop, determine the sensitivity.

3375. Wind your own multilayer coils

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-06 02:36:37 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <ab4q7l$8j2$1@knossos.btinternet.com>
Source record: 44317

NOW AVAILABLE ** New Program "MULTILAY.exe"

Program MULTILAY assists with the design and estimating performance of multilayer air-core coils, wound in bobbins or slots, often used in antenna circuits, preselectors, of radio receivers at low HF, LF and at frequencies down to audio in such applications as loud speaker cross-over networks.

Such coils are used in non-critical applications where high Q is not needed, precise inductance values are unnecessary and a solenoid is ruled out because of it's size in any case.

A hank of coax used as a choke in an antenna feedline can be approximated by this program. There are numerous other applications where home constructors may wish to wind by hand their own simple multilayer coils.

A coil of rectangular winding cross-section is specified simply in terms of inside diameter, outside diameter, axial length and the number of turns. Wire diameter and thickness of wire insulation is taken into account. A fairly wide range of coil proportions is covered by the program.

Inductance is computed to within 5 or 10 percent. Coils are not intended for precision applications and can be hand-wound. Scramble-wound is often acceptable. Self-capacitance, self-resonant frequency and Q are estimated with useful precision.

Use your imagination/ingenuity to find coil formers.

Download MULTILAY in a few seconds from website below. Run and obtain amswers immediately.

> Anyone know the model number?

Wish I could remember but it's been 20 - 25 years since it passed through my hands. About all I can remember is the sight of that air variable, longest one I ever saw.
This is a long shot but the surplus index in the back of surplus conversion manual #1 lists a receiver with the model # of ADF (Navy) and shows it to tune 15 khz to 1750 khz and has 8 tubes, 3 ea 6d6, 2 ea 76, 2 ea 6c6 and one 41. It gives no other information.

Dear Jack,

I just now saw a discussion on the AM Window, and it is way down the list of their bulletin board. Look for Class E AM rigs or some such thing. Here's the web site of one of the guys heavily involved with SS AM and PWM: http://www.netway.com/~stevec/ham/classe.htm This guy has been doing this stuff for years and years. Before he "went solid-state" he also built and documented tube PWM rigs as well. He's cutting edge and he knows how to build these things inexpensively, so look him up at the above link. His name is Steve Cloutier and his call is WA1QIX.
Some of his stuff can also be found at the AM International site: http://www.amfone.net/

Good luck, Lenny

Will this, or similar tubes (12AU7, 12AX7, etc.) work as a mixer at 146 MHz?

Jim
N8EE

3383. Re: 12AT7 Vacuum tube question

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-06 17:44:06 UTC
From: troglodite@aol.com
Message-ID: <20020506134406.07888.00012013@mb-mv.aol.com>
Source record: 44325

>Will this, or similar tubes (12AU7, 12AX7, etc.) work as a mixer at 146 MHz?

The 12AT7 works fine as a mixer for 2m. It was used in the Gonset Communicator and many other famous 2m rigs. The 12AU7 would also work, but does not have quite the gain. The 12AX7 is primarily intended for audio use, and is not suitable for RF.

Hello Brian , I have an excellent book on baluns and ununs
'Building and Using Balans and Ununs' by Jerry Sevick , W2FMI
These devices are meant for matching transmitters to antennas ,but smaller
varieties can obviously be used for your type of application.
An example in the book for a 50 Ohm to 600 Ohm transformer comprises a
1:1.33 Unun followed by a 1: 9 Balun.
There are also 50 ohm to 450 Ohm baluns described.
The principles apply to any application ,you could just copy the winding
ratios and use the correct toroid composition for the required freq range.

If you are interested I can scan the relevant pages in tif format ,attaching
these files to an e-mail . Just let me know

==========
No experience at all with the above ,but having read about the topic ,it
appears that low power operation in the QRP range does not affect a
pacemaker.

From: 4q <nospam@nospam-tek.com>
Message-ID: <ab8ubr0e2m@enews4.newsguy.com>
Source record: 44335

I recently built a transistor regen radio for the broadcast band. I use a MPF102 as the regen and I'm using a simple 100uH coil with 4 links for the anntena input and 6 links for the tickler. It works but I just happen to be about 5 blocks from KBRK which is one of the last of the big 50,000 watt am stations. They sit at 1420kHz but when I attach my anntena they cover from 800kHz to over 1600kHz. Oviously they are overloading the frontend. Is there anything I can do to limit the overload?

Don

I use dial.exe and panel.exe from www.qsl.net/wb8rcr, to print front panels on thin card for home built equipment. Applied with double-sided sticky tape and covered with transparent book covering film they give a reasonable finish in a short time. You can also use a sacrificial paper version as a drilling template to guarantee line up with the panel mounted components. The panel programme needs a postscript printer or down load Ghost view and Ghost script to use a non postscript device.
Regards

3394. Tuning dial / reduction drive mechanism

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-07 16:43:29 UTC
From: Hans Summers <Hans.Summers@Tudor.Com>
Message-ID: <abanc2$g965r$2@ID-61331.news.dfncis.de>
Source record: 44343

I had an enquiry about where to obtain the type of dial with reduction drive mechanism which I have used in my valve regen (http://www.hanssummers.com/radio/valve/intro.htm), transistor regen (http://www.hanssummers.com/radio/transistor/intro.htm) and my current polyphase-method SSB receiver (photos at the bottom of http://www.hanssummers.com/radio/cwtx/index.htm).

Here is a page with some photos of it from various angles: http://www.hanssummers.com/radio/polyphase/pix.htm.

Since I inherited these dials from my late Father I have no idea where to buy or obtain them. Does anyone recognise these drives and know a source?

Also, the mechanism of the dial in my current receiver project is filled with dust and grime and has a horrible backlash. Can anyone suggest how best to clean and regrease the bearings?

From: Bob Liesenfeld <robert.liesenfeld@neicoltech.org>
Message-ID: <3CD8195A.E5DA89F7@neicoltech.org>
Source record: 44337

Hey gang,
Looking through the copper pipe fitting section at the local Menards, I found a cool copper pipe fitting. It is a 6" length of 1/2" dia pipe, open on one end and turned down to a point at the other. I bought one and an end cap for about $1.50

Once home, I took a file to the pointy end to create a flat area about 1/8" in dia. Then I drilled a small hole through this flat spot clear through into the tube. Next I sawed the pipe in half as 6" was a bit too long.

Next, I cut a small piece of scrap PC board about 2" long, and just wide enough form a snug slide fit down the tube. Using a dermal tool, I cut several grooves through the copper foil to create isolated islands of copper. Next to the parts bin..... A .01uF cap, a hot carrier diode, and two series connected 2.2M resistors later, I had an RF probe a la http://www.io.com/~n5fc/rfprobe1.htm

The probe tip is a 1 1/2" finishing nail with a piece of spaghetti tubing over it that projects through the hole drilled in the end of the pipe. A small hole drilled in the end cap to pass the RG-174/U cable to the voltmeter was tack soldered to the end, while a lead terminated with an alligator clip is soldered to the outside of the tube for the gnd connection.

Less antenna? Perhaps a larger coil ~300uH and less C (higher Q tank) and looser coupling from the antenna.

Hi Jack,

I thought of that but I'm trying to keep the design as simple as possible.
But I have not ruled a notch filter out, something like an am band trap but
sharply tuned to 1420KHz.

The reduction gearing appears to be a standard Jackson Brothers 6:1 slow
motion drive. Not too sure about the dial itself but it looks
reminiscent of one I used to have fitted to a Geloso VFO.

You may have a hard time finding something with enough information to homebrew your supply, unless you are willing to do some work yourself on the design. That is, you _may_ find a schematic for a 1.5kW switching supply that will run from 220V/240V input, but likely it won't be 28V output. If you have enough understanding of how the supplies work and what the problems are building something with so much power, perhaps you can look at the web sites of the companies that make switch-mode power supply controllers. The application notes often will lead you through a design, and give you a sample circuit. Of course, it is a lot of power, so be careful. Instability in such a high-power system can lead to some large voltages, or large currents, or both. If you have never built a switching supply before, it may be a good idea to start with something smaller first.

Cheers,
Tom

I find it VERY hard to believe that a variable capacitor from a
TEN meter (28 MHz) transmitter would (could?) be very big at all!

I find it very hard to believe that in a civilised country and society
people think it necessary to keep arms and ammunition in there houses.
Where they live! Bloody hell the kids might get hold of them!

3414. TOKO Coils

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-09 01:08:43 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <3CD9CC9C.5DEADBA4@alma.demon.co.uk>
Source record: 44256

Any ideas where I can find information to identify TOKO inductors?

I have several sets of TOKO IF cans (Mainly 455kHz) with various markings on which I would be interested in identifying. Also a kind radio ham sent me some more TOKO IF cans, and I would like to identify them to see if there is a type which I currently need.

I've tried the obvious TOKO website, but I don't see any links to search any databases.

Do any suppliers have the information hidden anywhere?

I also know of www.bec.co.uk who do have some information on their web site, but only for their current product range.

E.g.

7mm - 113SN 2140 AG
10mm - KXNS K2241 HM
10mm - 154AC 7 A 6292 81281
10mm - ROS 6A 7686 79096
10mm - 5008 60HT

You would have thought with all that area to write on that the markings might in some way indicate the value of the inductors, configuration and internal cap value!

thanks...

3416. IF Stage - what type of transistor

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-09 01:36:56 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <3CD9D33A.CB16F39C@alma.demon.co.uk>
Source record: 44258

I am currently playing with a simple 455kHz IF stage. There will be two stages with IF cans yellow->white->black. I've found a few designs in old magazines (there's not much on the www) and I am curious as to why there are so many variations.

Which type of NPN transistor would be recommended for this task. I suspect that any old NPN will do, even BC109 or 2N2222. The designs I have to hand show: BF195; BC109; and BF185 (the can has an extra pin and can be grounded).

Any recommendations?

Other variations: output of IF can is used directly, or capacitively coupled; stage has no emitter resistor, or value 470 to 1k, sometimes capacitively decoupled. Now I know that the gain will vary...

thanks...

I find it hard to believe that in a civilized country and society
people cannot defend their lives and the lives of their loved ones by
whatever means without risking legal penalties nor display the flag of
their nation on their homes without government permission. What does
the previous reply have to do with home brew radios.

In order to put some actual electronics content in this, I just last
week finished the Small Wonders Lab PSK-20 kit. I'm using a dipole on
the ceiling of my apartment and it's a blast at three watts. Great
kit, I recommend it.

I've got a dual conversion that I have used over the past few years that uses a Phillips TDA1572 as the 2nd I.F. subsystem. This device has on-board AGC and demodulation, and a buffered 50 Ohm I.F. output for feeding SSB detectors, etc. I would be glad to e-mail .gifs of the circuit details.

I've always found the 2N3563 to be excellent in IF strips. It is
overkill for a 455kHz IF amp though. The 2SC710 is also a good choice.

Ramsey electronics made a cheep kit a few years ago that's exactly what
you're looking for.
It used 2 common TIP30 transistors as finals, If you can't find the kit you
may want to search for schematics and build from scratch, the design was
very simple. I think it took 2W drive for 30W out.

> the functionality would definatly work, and with proper antennas, I

> might even get the distance (although no line of sight might cause

> problems at those frequencies?)...

I don't think distance will be a problem. I access the internet via a
Wireless LAN at 2.9ghz. These wireless cards typically have a range of about
200 feet used on an indoor network, but fed to a small parabolic, I access
my provider at over 3 miles away with a Virtual T1 connection. The wireless
cards typically sell for under $100 at your local office supply store.

Line of site is a potential problem. The installation people had to raise
the parabolic an additional 10 feet to clear a neighbor's rooftop several
doors away from me.

While 2.9ghz is a part 15 band and does not require any license for
operation, it sure seems to open a lot of possibilities for experimentation.

It is important to know what kind and how you are going to apply
the AGC to the IF stages. The germanium PNP transistors used
in most consumer sets are intended to work with the detected AGC
voltage being fed back to the biasing.

Yes, this is the problem, and if you check few months back you will
see several more replies on this matter, but you may probably not find
any of your coils listed, I have several douzens of TOKO coils, but
not found any of mine listed. So perhaps I have to make my own list
based on measurements, hi.
Believe it was some info at SM0VPO or similar site, but they didn't
apply for many of my coils

It is also a problem to identify coils from the way they are listed in
the price-list. Amidon had a list, those catalogues may be worth a lot
today, I also have some older lists from late 70's which should be
scanned and decoded

In Europe we have a large range of inexpensive low feedback-
capacitance RF/IF transistors, so you don't have to choose amongst
devices which may oscillate instead of amplify. Also used 2N3563 back
in 1967, but such old devices are usually not cheap.

Some of the most used npn devices are BF115 BF167 BF173 BF184 BF196
BF197 BF198 BF199 BF224 BF240 and the pnp devices BF324 BF479 BF679

3440. Terminating HC4066 Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-09 22:38:24 UTC
From: la8ak.xnd@online.no
Message-ID: <3cdaf576.772187797@news.online.no>
Source record: 44282

Have found the 4066 mixer interesting, particularly for the low drive level, and it may simplify some of my applications. Several different applications have been found, but some points remain unclear.

Some application uses 50 ohm on the RF/IF ports, while some say 200-300 ohm or higher is better compromise based on series resistance and possible supply voltage. Is it really necessary to have any defined load at all on the output? Could it just be an LC-circuit of which impedance can vary?

Some applications have DC-termination on IF port, but I don't understand the need as long as it is properly DC-biassed on the RF port.

An interesting application is found on http://home.snafu.de/graff/sbt40.pdf it seems that the IF termination is 400 ohm for the AC component, but it is no DC-termination. The solution to avoid input transformer or link also seems to be a good idea.

I'd like to rebuild my BC-348. If I remember correctly there were two favorite conversions:

1: Rebuild the detector as a regegenerative detector.

2: Repace all of the vacume tubes with one or two IC's.

Anybody have a line on where i could find either article, I've lost my copies.

tnx

Source record: 44284

Hi,
I have done rather extensive tests with both the HC4066 and the HC4053 used as a mixer. These tests include checking mixer output (IF) IMD at various impedances. Best IMD is achieved with both IC's when all ports are terminated in 50 ohms, exactly like the passive DBM requires. My particular application was for an LF to HF upconverter. I initially tried the "standard" diplexer at the mixer output, but further tests showed I could not achieve a flat IF response--the diplexer had a narrower bandpass than the 500kHz I wanted. I ended up terminating the mixer with a simple wideband one-transistor amp, with 50 ohm in/out impedances, and adjusting its gain to give an overall mixer conversion loss of 0 dB.
The mixer input was fed with a wideband ferrite trifilar transformer; the oscillator port from an HC04 oscillator output (not necessarily 50 ohms).
Performance of this upconverter is good.

I have a JWMiller catalog from the early 80's that had their
adjustable ceramic core parts along with the number of turns on
those cores, which is very handy if you want to wind up some for
your own projects. I have it scanned in .pdf format and will send
it to someone who has a ftp site and makes it available to others.
I also have some older Amidon catalogs that needs scanning in.
If anyone has the space on a ftp site and wants to host the files,
get with me and we'll work out the details (file size and such).
Mark

Perhaps I should add, the IC mixer was comparable to a passive DBM fed
by a +7dBm LO input, not a high-level DBM.

I still have a project for sale. It is the 6 meter AM transceiver put out by the IA QRP club. I have the board, the pots, a used CB modulation transformer, the modulator chip, the crystal filter (the good one), and the coil form. Make me a decent offer.

I have a Ten-Tec model 250 power supply. It puts out 12 VDC @ 8 amps (non-regulated), and 12 VDC @ 1.5 amps (regulated). I don't know what rig it is for. It has a lot of "wear" scratches on it but seems to work fine. I don't know what it is worth. Make me a decent offer.

I have three NOS Dow Key Coaxial Relays, DK60-G2C. They are 52 ohm, rated for 1000 watts. The coil is 6060 ohm, 110 VDC(?). They have a set of DPDT auxiliary contacts. This is the internally shielded model. Make me a decent offer.

I'm a motivated seller. I have a Timewave DSP9+ that needs $60 worth of repairs. XYL is not too thrilled about getting it fixed since I paid $40 at a hamfest and it didn't work. Ouch.

Huh? The favorite conversion would have been to do the bare minimum
to make it functional. Not to keep the receiver "pristine" but
because it was more or less fine to begin with, and what's the
point of doing more than necessary.

I've never seen mention of making the detector regenerative.
And "replacing the tubes with 1 or 2 IC's" would never have
been popular, because by that time the receiver was pretty much
out of fashion. The popular conversions would have come shortly
after the war, when the receivers were popular and current.

Of course, plenty of people must have done all kinds of things
to those receivers, but you wouldn't call them popular.

Hank Cross, W1OOP (whatever happened to him?) did write
about solid-stating the BC348 in Ham Radio magazine, in 1969.
I think the only IC was the audio amplifier, since ICs were
still a relatively new thing in hobby circles.

Source record: 44291

A lot of the early (and for that matter more recent) conversions from hollow-state to solid state did terrible things to receiver performance, particularly intermodulation. Wes Hayward, W7ZOI had a photograph he would show at the beginning of some of his talks -- a KWM2 in a trash bin marked "Old Junk". It was one that had been modified to solid state, and it had dismal performance.

The BC-348 is something of a collector's item today, and getting to be more so all the time. By today's standards, it's not much of a receiver. If you modify it, you'll have a receiver that's still not much by today's standards (and very probably worse than before), and it won't even be interesting as a collector's item.

Roy Lewallen, W7EL

Source record: 44292

The on resistance of these devices according to the data sheet is about 20-30 ohms, depending on supply volts etc. They could be regarded as a resistor in the circuit consisting of source impedance/mixer/load impedance at the LO frequency. Thus their response will depend very much on load impedance. For example, using the Tayloe setup with a large capacitor as the mixer load (ie an audio low pass filter) the mixer acts like a very sharp bandpass filter. The mixer presents a relatively high impedance to the RF input at LO frequency (and harmonics thereof) and low impedance at other frequencies. It would presumably look like a switched capacitor filter (which it is) at audio.
Rod VK6KRG and I has done some experiments with the Tayloe circuit (ie 4 of these mixers switched by a quadrature commutated LO). If the 4 phases are mixed back up again to RF with a second set of quadrature mixers, the result is a filtered version of the input with a *very* sharp bandpass - -20 dB at +\- 50 KHz, regardless of LO frequency. These results could be achieved at 20 MHz. (and presumably higher with the right mixer) There were opposite sideband effects but this could presumably be improved with good circuit balance. We made no attempt to get ideal balance.
I would be interested to know if anyone has done a rigorous analysis of this circuit using a Spice package or in real life

Richard

Source record: 44293

Hi,

Building a new triode PA (grounded grid) with GS35B I got the following question:

What will happen in case the filament supply (12V with GS35B) breaks down (0 V)?

Of course no anode/grid current and corresponding output can be obtained, but is there any change of damaging the filament or tube ?
Basically, do I need to switch of anode voltage ? or prevent RF drive to be applied in such a case ?

Hope someone acan give me some hints ....

Thanks in advance,

Carel

Hi Hans

These or similar where made by Mentor, Germany AFAIK.
They have a website now http://www.mentor-components.de
Look under "Produkte", "Skalenscheiben", "Knï¿½pfe",
"Untersetzungsgetriebe".
Of course the kind of combination dial/gear isn't made anymore but
you might find a replacement for the gear. They have
Art.Nr. 100.2N 6:1; Art.Nr. 100.5 10:1 and Art.Nr. 110.1 36:1
Also nice knobs with integrated gear for 6:1
I couldn't see any english pages on their site and also
their webpage is badly broken. It only works with IE. No Netscape,
no Mozilla, no Konqueror and no Opera :-((
I hate this!

Best Regards, Ike

3454. Help with Gould sweep generator

I'm in desperate need of a service manual for a Gould Advance sweep
generator, model SW100.
I've searched the web over, found one guy in Europe that had one for sale,
but was searching
for a manual as well.
If anyone has ideas where I might find one, I'd be very grateful (and
indebted to you for life).

Thanks!
Mark

3455. Re: Tube filament protection question

When the tube is cold, you can't really harm it. I wouldn't worry about the situation you describe.

Of course, if you lose filament power while the other voltages are applied, and the filament cools off, there may be some danger at that time, a cooling filament with considerable plate current.

Most all high power tubes can be damaged if plate voltage is applied
before the cathode comes
up to operating temperature. Not familiar with the tube that you
mentioned but if it is an
indirectly heated cathode type (not just a filament) then there is
usually a warm-up time of 60 to
90 seconds or more required before any other voltages are applied.

If it is a directly heated type (just a filament) then usually
filament and plate voltage can be
supplied at the same time as the tubes heats up almost instantly.

Look at the specs on the tube. They will tell you how much warm up
time is needed.

Smaller tubes that operate with plate voltages under 1000 volts can
usually have plate voltages
supplied with the cathode cold and no harm is done.

Without the heater, the cathode emission with drop to 0, so the tube goes
"dead".
I would not worry about it much. It would be better to use a "latching
relay" in the AC primary, so if the AC main drops out, the amp shuts down,
and no damge can be done.
I have seen amps that were severly damaged when the user was transmitting,
when the AC main dropped out and came back a few milli-seconds later.

>>I find it VERY hard to believe that a variable capacitor from a
>>TEN meter (28 MHz) transmitter would (could?) be very big at all!

>It has two 833a tubes connected with it, if you don't believe me, I posted
>to find help for this not to try to be discredited, Barker and Williamson
>was no help, and they even manufactured it.

I had no intention of discrediting you. I thought you asked for help in identifying a "very large" variable capacitor, and I just tried to indicate (apparently poorly) that a capacitor used in a 10-meter xmtr might not be all that large.

Now that you've given the additional information that the xmtr has two 833A's, a tube manual shows that their maximum frequency for full rated is 30 MHz, so 10 meters is at least a possibility. The manual also shows typical plate voltages of 2000 (telegraphy) and 2500 (telephony), so capacitor spacing would need to be considerable (maybe a quarter-inch between a pair of adjacent stator plates?). But capacitances of 50-100 pf fall right in the center of what might be used at 28 MHz, and variable capacitors of that size and spacing are not what I'd consider to be "very large". (There's always the chance, however, that what **I** think of as "very large" and what you think of as "very large" are entirely different beasts!-)

So no "put down" was intended.

Are you aware that the FCC requires external power amplifiers be certified, and that as part of that certification, it is necessary to prove that:

- The amplifier cannot reasonably be modified to be capable of operation between 24 and 35 MHz
- The amplifier must require at least 50 watts of drive.

If you want to take a commercial amateur amplifier and modify it for operation at 27 MHz it's going to be tough slugging. Not only do you have the frequency problem, but you have the drive problem, too.

If you want to modify a 20 meter amp to work on 30 meters, it should be pretty simple. In fact, if you are licensed to operate on 30 meters you already know how. Going up in frequency more than a little can be a problem if it's a solid state amp. Transistor gain decreases with increasing frequency, so a single band amp may take more than some simple modification.

..

3463. Preselector with image notch??

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-11 00:41:17 UTC
From: John <john@clavin.freeserve.co.uk>
Message-ID: <abhpth$ek1$1@newsg1.svr.pol.co.uk>
Source record: 44205

Hi Guys,

In persuit of good image rejection in a HF receiver with a 455Khz IF, I am using a 3 stage preselector. What I have in mind to enhance this is a stage of image "notch" filtering just after the RF amp and before the first mixer. I'll use a second cap on the VFO to a tuned circuit (tuned 900Khz off) routing the image to ground.

Can anyone see any problems with this? ..apart from the fact that I would benefit from using a much higher IF!

Cheers,

John, G0WPA.

thanks for the reply.
Want to use Philips or Motorola HC4066 on 12V supply. The maximum
signal level is 4.28V RMS. Using 200 ohm impedance the power level is
max 92mW or +19.6dBm, 6dB higher with 50 ohm RF/IF termination, and
still 16.6dBm with 400 ohm terminations.

My idea is to use a grounded gate amplifier with MPF105 or BF245B.
In the application as mixer from 136kHz to 60kHz I don't really see
that such amplifier could cause termination problems provided the
mixer sees 200 ohm for all mixer products, HF and VHF would be
different.

Understood that you ended up without diplexer and the 50 ohm amplifier
is capacitively coupled to the mixer output(?). How important is
DC-return from mixer output?

wonder if somebody has tried 2/3 4053 instead of 4/4 4066?

Hi,
My experiments were with 5 and 6volts, VCC on the IC; I didn't try 12volts. Performance was somewhat improved (better IMD) with 6 volts, so I would assume significantly better at 12VCC. That is a huge max input signal you're expecting. A high-level DBM (+23dBM LO) would be straining to stay linear with such a large input. I would guess this IC mixer will not be linear with such a large input, but perhaps your application is not as a receiving mixer but as a transmitting mixer, where strict linearity may not need to be as desirable.
The following IF amp has to be capacitively coupled, in order not to short out the transistor's bias.
The IC mixer must also see a DC return on the mixer output. It's biassed at 1/2 VCC. I used 10kohm to the mixer output, for isolation, as the following IF amp provides the 50 ohm termination for the mixer.
(The complete circuit can be seen in the article in April 2002 QST magazine.)
My experiments used both the HC4066 and 4053, with identical results.

John:

The concept is valid but I see some difficulty if the "second cap on the VFO" means you want the image reject notch to track 900 kHz away from the desired freq as you tune the VFO. It is certainly not impossible to produce such tracking, but it will not be a trivial task either. There may be some resources to assist you in this, but I am not aware of any...perhaps someone else will offer something helpful.

If you are committed to a 455 kHz IF, you might consider a dual conversion scheme to improve image rejection.

Was it broad? Unless I'm confusing it with something else, it had a
915KHz IF, but single-crystal filter (and I've read that the crystal
didn't age well), so could it have been that bad?

On the other hand, good design should be whether the unit fits
the application, not whether it fits a fixed set of spces. A broader
IF probably wasn't too serious, because it was channelized operation,
rather than the free-for-all of a ham band. And a broader IF would
mean it would take longer for the signal to drift out of the pass-band.

This reminds me of those six and two meter transceivers that were
described in Communications Quarterly some years back, was it Rick
Littlefield or Peter Bertini? They were basically an update of those
old AM rigs of the Gonset Communicator era. It still needed a broad
IF, because like it's predecessors the local oscillator was just
a tuneable oscillator. But it used an FM-bandwidth crystal filter,
allowing for a higher IF (and better image rejection) without the
wider passband that would occur if only IF transformers were used.
And it probably had better skirt selectivity. "A piece of junk"
if compared to a modern SSB transceiver, yet the design served
it's purpose, a relatively simple circuit that was well balanced
between trade-offs and performance.

Source record: 44212

There is an old trick used in high performance receivers in the past with a low IF. The following description is on the Tandberg Huldra 4 (about 1950) and could easily be applied to amateur bands. The Huldra 4 is a receiver with 11 bands, of which 8 are band spread short-wave bands. Its intermediate frequency is 455 kHz and the image frequency is below the desired frequency. It feeds the RF signal to a parallel tuned circuit via a series capacitor. Since the parallel tuned circuit will be inductive at the image frequency, the series combination can be made to resonate at the image and suppress it. This is implemented with 1% or 0.5 pF tolerance series capacitors and works on the 7 lowest short-wave bands, from 49 m to 13 m. On 11 m, the resonance is not sharp enough, so it is not used. In this way the receiver has variable traps for suppression of the image, with tuning that tracks the signal frequency.
See also my Tandberg page at www.qsl.net/la3za

Hey,
I need to build a notch filter for one of my antennas since I live
less than 1km from a powerful paging transmitter on 168-170MHz.
I want to put the filter in the same box as the amplifier so I cant use
a stub filter.
I was thinking about etching a microstrip filter but I have no idea
of how to calculate this, or do you have any other suggestions for
a suitable filter? Any working ideas are welcome :)

_____

Why not? If we're talking about a 1/4 wl piece of coax, open at one
end, it can be coiled up pretty tight in the box and still work just
fine. Or did you mean something else?

In any event, a series- or parallel-resonant trap can be inserted in the
appropriate location and should work fine too, and be easier to tune to
the exact frequency.

Be thankful the transmitter is a km away and not next door. :-)

Hei

har du jobbet p&#65533; Tandberg Radio? Har pr&#65533;vd &#65533; f&#65533; tatt opp med NRHF at en burde f&#65533; noen fra de gamle radiofabrikkene til &#65533; fortelle om forskjellige triks de har gjort i produksjonen for &#65533; f&#65533; utstyr til &#65533; virke.

Til det blir en m&#65533;tt med det noks&#65533; negative holdningen - at det ikke finnes noen &#65533; sp&#65533;rre - og en kan undre seg hvorfor en slik forening ikke har innsett at det ville v&#65533;re mange ting som var interessant &#65533; finne ut av. En annen ting er hvorfor Radionette Kurer med D'96-serien har positiv tilbakekopling i f&#65533;rste MF trinn, det st&#65533;r ikke p&#65533; skjema, en form for fast innstillt Q-multiplier.

At the price of considerable added complexity, how about an image rejecting mixer? You should pick up as much as 30 dB image rejection, dependent upon phase balances.

The problem with stubs is that they are broad and not very deep (even w/
hardline)
See our asymmetrical notch filters at http://parelectronics.com or the
Universal Radio, Grove Enterprises or AES site. Very steep and deep
notches.

Before you rule out any filtering approach, you really need to
determine how much rejection you need.

Use a sniffer and measure the rejection required with an attenuator in
the ant line to your Rx, with a sig-gen into the tap of the sniffer.

>I was thinking about etching a microstrip filter but I have no idea

usually a small helical resonator will give quite a decent rejection.

Hi,

Maybe you have seen my site before but I will post it here again because
I have just completed a major redisign of the web site.
It gives a detailed description of my homebrew receiver 0.3 - 30 MHz.
Also I have added the technical description of the audio processing board
which was long overdue.

members.aol.com/gapershi/radio.htm

I hope other homebrewers can document their projects in a similar manner.
Oh, and before yo ask, no I am not a ham.

> I know that some of the Ramsey amplifiers can be modified to operate on
> different frequencies. I just don't know where to get the information. Can
> you help?

I think the Ramsey amp is relatively broadband. In any event, as long as you are not going too far in frequency, all you really need to do is to recalculate the output network for the new frequency. There are about a zillion programs out there to do this.

It's hard to understand how Ramsey gets away with selling their amp, however, on other reflectors it does seem like this amp takes quite a bit to get it operating on the frequencies it was intended for. Plus, it's not a lot of power so charlie probably looks the other way.

> Also, I'm not operating in the USA so American law has no bearing.

Well, whether you are operating under US law or not, most of the reasonably priced amps are marketed to U.S. hams, so they are built to comply with the FCC regs so they can sell them here.

> Is there an ET out there?? I'm willing to pay.

Amplifiers are relatively simple. If you were to get a copy of The ARRL Handbook you would find projects for a half-dozen amps along with enough information to build one on the frequency you want.

Also, at www.hfprojects.org is enough information to build a pretty nice amp. You won't be able to get in on their parts buy, but there is a bunch of information on that site. Plus, there's not a huge amount of theoretical info there, so you would have to make some assumptions on changing the frequency.

What are you trying to do? If you are looking for relatively low power like the Ramsey amp, it can be a pretty simple thing. But as the power goes up, and as the frequency goes up, it gets harder. Although at some VHF ranges there are amp components that can be assembled into an amp with relatively little pain, again, depending on the power level.

Hans,

Many old ARRL Handbook projects used these dials in the 1950's. I believe
that Millen and National both made versions. I occasionally see on eBay and
at Hamfests (Rallys - UK).

I am building an underwater robot for a university project and i want to put a video camera on board. I want about 1 frame per second. What radio frequencies can be transmitted underwater and recieved either above the surface or with an aerial under? At these frequencies would the availiable bandwidth cope with a low res (300x300 pixel sampled at 8 bit resolution - meaning a total size of 720kbit) image at this kind of refresh rate? Can a transmitter/reciever pair for this be bought, or built, for a reasonable price? If so please could you point me in the right direction? Any help would be greatly appreciated.

Thanks in advance

Matt

I have one -a 3586B, almost brand new! I even changed the tuning knob to a spinner to facilitate faster tuning. It is a great receiver, accurate and sensitive, a great VLF receiver, but it has some disadvantages:

1. Limited memory storage, limited in capacity and retention time. Be sure to replace the NICAD battery ($30 from agilent) before it leaks on the Power supply card.

2. There is no form of AGC, This is test equipment, the circuitry is designed to accurately measure input signal levels but apparently has no control over the audio gain. Work arounds are to turn off the autoleveling feature or to set the receiver to "average". I am looking into a simple add on AVC circuit to tap into the audio output amplifier. The output power of the amp is a bit low, and the speaker small.

3. There is no squelch circuit.

4. Tuning steps must be programmed in from front panel, the tuning is a bit slow and clunky but gets you to where you need to go.

There are three different versions an A, B and C. The catalog describes them. I think the C has fewer test features. The A and B differ in that the B has "C" message filtering. The input assembly uses funky video connectors and is 75ohm on the A and B models. I removed the unbalanced input connector on mine and replaced with a BNC, With some washers, I was able to shim the BNC connector to project out the front bezel same as the factory installed version on the C model.

I am interested in hearing from others using these.

Thanks for the replies guys,

What I had in mind Roger was to align the tuned circuit at the top end of the RX range where the 910Khz image may otherwise be a problem. If the tracking was less accurate at the lower end it should not be a problem as the tighter filtering of the pre-select would probably have removed most of the image anyway. My main concern with using a dual gang cap was inadvertantly coupling some VFO signal to the mixers RF input.

What Sverre Holm suggested also sounds interesting. Im presuming that the series cap would need to be variable, because no matter what the received frequency, the perceived value of inductance would be a fixed value at the image freq(i.e the inductance would be a result of the 910Khz difference between the wanted and image freqs). This needs some experimentation I think.

As for using an image rejection mixer?, well i've thought that it must be possible using mixers or Q-multipliers and i'll certainly do some searches for info on them. 30dB of image rejection would be total at HF where noise levels are high anyway so that sounds like a definite possibility but the concept of phase balances is just a little scary :)

Thanks again guys,

John G0WPA, G-Qrp Club 8760.

RADIO HABANA CUBA
DXERS UNLIMITED

WEEKEND EDITION
SATURDAY, MAY 4, 2002

By Arnie Coro CO2KK

Send your comments, questions and ideas to: arnie@radiohc.org

Hi, amigos radioaficionados all around the world! You are now listening to the weekend edition of your favorite radio hobby program, this is Dxers Unlimited, and I am Arnie Coro, radio amateur CO2KK, your host here in Havana ready to share with you all about seventeen minutes of all radio hobby related information....

Here is item one: Another upsurge in solar activity, and heliosismic data show that there are lots of sunspots on the farside of the Sun, so amigos, we may be seeing yet another solar rotation with a lot of activity!!!

Item two: Specialized amateur contests that do not disrupt your weekend with the family and friends are becoming more and more popular, for one very good reason: you enjoy the thrills of a real contest for a few hours, and then the rest of the weekend can be spent with your family. Not too long ago, a ham radio friend told me that the four- or six-hour-long contests do require a lot of skill, especially those that let you select the four- or six-hour operating period!!!

Item three: FM band Dxing is becoming more and more difficult all over the world due to the continuos increase of the number of low power local FM broadcast stations that are receiving licenses from the radio regulating authorities. Even a 10 watt local with a 6 dB gain antenna will make DX impossible on its own channel and at least on the first two adjacent channels, that depending on how close to your location the low power FM station is.

Nevertheless, dedicated FM broadcast band Dxers are learning some of the tricks that AM band DXers use, like waiting for off-the-air hours that station engineers need to do equipment maintenance... By the way, the FM broadcast band sporadic E DX season has just started, but so far, the openings are few and far apart from each other.

Item four: Homebrewing your radios is a lot of fun, and there is nothing like listening to DX with your homebuilt receiver, or like working DX with your amateur radio rig which you have just finished building. More about homebrew radios later here at the weekend edition of DXers Unlimited, amigos...

And, as always at the end of the show, be ready to copy Arnie Coro's Dxers Unlimited's exclusive and not copyrighted HF plus 6 meters propagation update and forecast. Margarita

Delgado is my sound engineer and producer at studio 7, this is Radio Havana Cuba....

Amigos, you are listening to the weekend edition of Dxers Unlimited, and here is our main feature for today: Arnie's advice about homebrewing your radio equipment. First things first... so don't attempt to start your homebrewing with a very sophisticated project, or without having the adequate tools at hand including, of course, your digital multi-meter!

You may perhaps want to start learning how to homebrew your radios by building one of the many kits now available, and as a matter of fact, that is an approach that I do recommend, because kits are an excellent way of learning about electronics.... Unfortunately some of the new generation kits are rather difficult to assemble due to the use of very small electronic components placed too tightly together, thus making your job of putting together the kit a lot harder. Here in Cuba, radio amateurs build a lot of their equipment, and something we all have learned is to homebrew our radios without any attempts to make them miniature sets!!!

Leaving enough space between the resistors, capacitors, integrated circuits, transistors, coils, crystals and other components has proven to be a very good idea, because it is a lot easier to put them together into something that will work, and also because when there is a breakdown, your homebrew set is a lot easier to repair...

Some Cuban amateurs have a second transceiver always ready for emergency communications, and that second radio is typically a version of the JAGUEY solid state double sideband transceiver, running anywhere from 3 to 10 watts, enough to communicate using a Near Vertical Incidence Skywave antenna system on the 80 and 40 meter bands... The homebrew JAGUEY is a quite straightforward design that allows you to upgrade the transceiver to a single side band set if you are able to obtain a single side band filter at a later date...

As a good friend likes to say, when you use a low power double sideband transceiver, no one realizes that you are also transmitting the unwanted sideband, as the other station's radio provides the filtering to pick up just the sideband in use on that specific band... In other words, if I am operating CO2KK with my JAGUEY on 40 meters, other stations using Single Side Band rigs will only pick up my lower sideband, as their transceivers will just chop away the upper side band when receiving....

Well, as you may realize, homebrewing a low cost double side band transceiver is not only a perfectly feasible project, but also one that will make your station ready to deal with communications emergencies, due to the fact that the JAGUEY needs just 12 volts from a battery to operate, and it draws very little current, even when transmitting. More about the JAGUEY and its most recent improvements in a few seconds, when Dxers Unlimited's weekend edition continues...

You are listening to Radio Havana Cuba, and amigos, if you happen to own a receiver capable of receiving single side band signals, try listening to our 11705 kiloHertz SSB broadcasts in English that start at 0100 UTC and last until 0500 UTC. Again our 11705 kiloHertz SSB is operating using upper sideband at reduced carrier, so that you can zero beat to the residual carrier for perfect reception... For those technically minded, we are running around 20 kiloWatts Peak Envelope Power, or PEP, with -12 dB carrier level, and the antenna is an array of dipoles beaming exactly North of Havana...

And now more about the JAGUEY double side band and CW single amateur band transceiver and its latest version... Among the most recent upgrades are the use of a triple tuned bandpass input filter and attenuator, which makes reception a lot better... Receiver incremental tuning, or RIT, was also added to the basic JAGUEY design, and the CW keying was improved

by using a PNP transistor with wave shaping to key the rig...

Also, the NEW JAGUEY has an optional pair of audio filters, one for SSB and the other one for CW, so that the operator may switch from one to the other as required. The NEW JAGUEY also uses a simple but effective transmitter audio compressor that improves the punch of the signal quite a bit. And last but not least, some of the local enthusiasts have now built a very low-cost linear amplifier that uses recycled vacuum tubes to increase the output power of the JAGUEY to anywhere between 20 and 50 Watts...

One very interesting feature of the NEW JAGUEY is that once the newcomer to the amateur radio hobby finds a single sideband filter, the NEW JAGUEY can be readily adapted to be the "tail end" of a single sideband transceiver, so not even one component is lost from the original project. AH, and before I forget, the NEW JAGUEY is a very, very, flexible design because, for example, the receiver audio can be implemented with no less than three different circuits, a straightforward three transistor single ended audio amplifier, a more sophisticated push pull design using discrete components as the first one just mentioned, and the classic JAGUEY receiver audio module that uses a low noise audio transistor coupled to an integrated circuit audio amplifier, the TBA810 or A210 that happens to be plentiful here in Cuba...

Si amigos, yes my friends, oui mes amis... Homebrewing your radio gear is a lot of fun, and when propagation conditions are not good, then you just plug in the soldering iron, and start building your next project... By the way, I am working now on the NEW JAGUEY PROJECT circuit diagram and operating manual, and as soon as they are both ready, they will be posted at our Dxers Unlimited website for you to download....

One of the outstading features of this unique radio amateur transceiver is the fact that I have included a complete list of parts with sets of values that can be used without the circuit suffering from any degradation.... In other words, you may find right next to each component -- be it a resistor, capacitor, transistor or IC -- a number of options that you can use, making construction a lot easier... As many of you who already have built electronic equipment know very well, the lack of a specific value resistor, for example, can bring the whole project to a standstill, so is was why I spend a lot of time testing each NEW JAGUEY module to learn how the parts values could be changed around without degrading the performance of the transceiver!!!

The NEW JAGUEY receiver chain uses a switched three, four or five position RF input attenuator, followed by a two or three tuned circuit band pass filter, feeding a grounded base or grounded gate RF amplifier stage, that delivers its signal to a double balanced mixer acting as a product detector... audio from the product detector is fed to a low noise audio preamplifier that in turn feeds one of the two audio filters, which in turn feed the audio power amplifier module... The VFO is a very straightforward three transistor module, of which there are three different versions that you can choose from, depending on the parts that you have available. As a matter of fact, newcomers to the amateur radio hobby may build just the receiver part of the NEW JAGUEY and start listening to the 80 or 40 meter bands to pick up CW practice, and then after they obtain their license, they can build the transmitter module!

I'll tell you more about the NEW JAGUEY in our upcoming mid-week edition of Dxers Unlimited next Tuesday and Wednesday UTC days, when I will describe the transmitter chain of the NEW JAGUEY, the Cuban-designed, low-cost double sideband and CW transceiver....

And now, amigos, as always at the end of the show, here is Arnie Coro's Dxers Unlimited's HF plus 6 meters propagation update and forecast:

Solar activity is MOVING UP AGAIN, and both the number of sunspots and solar microwave flux are increasing... Heliosismic data show that we will have from a week to ten more days of higher activity, and don't be surprised if yet another big solar flare erupts during the next few days.

We all hope that the summer sporadic E season will finally take off, too. The best band for amateur radio Dxing during the local daylight hours should be 15 meters, while nightime DX on 20 meters is going to be plentiful for the rest of the summer...

RADIO HABANA CUBA
DXERS UNLIMITED

WEEKEND EDITION
SATURDAY, APRIL 27, 2002

By Arnie Coro CO2KK

Send your comments, questions and ideas to: arnie@radiohc.org

Hi, amigos radioaficionados around the world! Nice to have you all listening to radio hobby program coming to you from Havana. I am Arnie Coro, radio amateur CO2KK, and as always it is my pleasure to share with you about seventeen minutes of all radio hobby related information!

Item one: Solar update: After a very active last week, now the sun seems to be taking a rest, and the daily sunspot numbers and solar flux have taken a nose dive. At the same time we are enjoying a period of very quiet geomagnetic activity, quite a change from the past two weeks...

Item two: One of the most fascinating ways of enjoying our wonderful hobby is .... YES, one of the most wonderful way of playing with our radios is to organize a DX expedition... go to a remote location, install your radio equipment, have yourself a nice time and make a lot of ham radio operators around the world very happy too when you give them the opportunity to work a new country, or in the case of VHF-UHF and Microwaves a new Grid Square...

Today I have here with me at RHC studio 7 an amateur radio operator from the United States, his name is Frank Smith and the world knows him for organizing some very interesting amateur radio DX expeditions...

Frank will answer my questions about this very interesting topic so that many of you will perhaps start thinking about organizing your own Dx expedition soon!!! And as always, at the end of the show, I will provide you with the most up to date HF plus 6 meters propagation forecast... Margarita Delgado is my sound engineer and producer, I am Arnie Coro in Havana back with you all in a few seconds....

You are tuned to Radio Havana Cuba, and this is Dxers Unlimited's weekend edition... today with a special interview to Frank Smith, an American radio amateur visiting Cuba... Frank, let's start talking amigo...

[The live on-air conversation is not available in this transcript. Please contact Arnie at arnie@radiohc.org for more information. -- NY Transfer]

3489. RF connectors on older EICO test gear

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-12 07:27:54 UTC
From: Jochen Roth <jochen@this.is.invalid>
Message-ID: <abl5hqfvf1@reader1.panix.com>
Source record: 44231
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

Hello,

I have an old (50s) EICO signal tracer and a couple other pieces of equipment from around that time, like a VTVM.

I want to find out the specification for the connectors used by most of these pieces, and perhaps a source. I'd rather keep the old connectors than replace them with newer BNC pieces.

Size is similar to PL259, but with a shorter thread, and without the prong that the PL259 type connectors use. Likewise, the jack does not have a hole. The hot connection is made by the solder ball created by soldering the cable to the connector.

Thanks in advance for any help.

Jochen

3490. CQ Orlando Wtd TT1380

I have a ham work colleague visiting Orlando for the next 4 days and I would really appreciate it if anyone has an unbuilt TT1380 80mtr transceiver kit and would be prepared to deliver one to his hotel (he can't drive). Of course I would pay the costs.
Please let me know if you can help out.

Conventional radio doesn't work under water. The military use very low
frequency signals which do propagate OK for communication with nuclear subs,
but need *very* long antennas to transmit them. You will need some other
form of transmission which can be modulated such as sound or light.

There has been and is now lots of work going on in this area.
Search under ROV (remote operated vehicle) and AUV (autonomous
underwater
vehicle) and you should find something interesting.

You will probably need to use an ultrasonic link if you need the robot
to be wireless. If you can use an umbilical then it is much easier as
you can get plenty of bandwidth on simple wire. The working ROVs out
there generally use fiberoptics and will have multiple channels of high
resolution
video and telemetry in addition to the power and control. When you
remember
that many of these ROVs are working to 10,000 feet or more underwater
you
can see that this is not simple junk.

You might want to check out JW Fishers;
http://www.jwfishers.com

Look also at commercial diving sites. Lots of work formerly done by
divers is
now done or supplemented by ROVs.

michael (electronics tech and commercial diver in central FL)

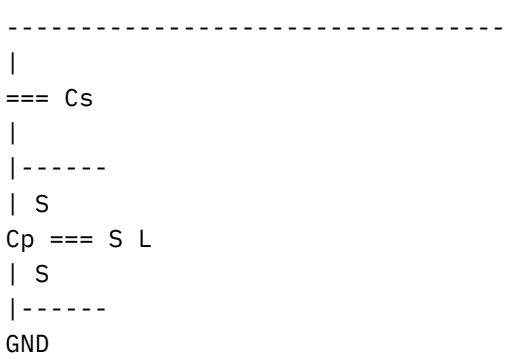
No, the series cap is fixed. The input circuit is:



where the Cp is variable. The variable Cp both tunes the parallel resonance (with L) and the series resonance (combination of Cs and Cp//L). For a narrow band such as a broadcast band or an amateur band, the tracking is good enough.

> Hi, amigos radioaficionados all around the world! You are now listening to
the weekend edition of your favorite radio hobby program, this is Dxers
Unlimited, and I am Arnie Coro, radio amateur CO2KK, your host here in
Havana ready to share with you all about seventeen minutes of all radio
hobby related information....
>
> Here is item one: Another upsurge in solar activity, and heliosismic data
show that there are lots of sunspots on the farside of the Sun, so amigos,
we may be seeing yet another solar rotation with a lot of activity!!!
>
> Item two: Specialized amateur contests that do not disrupt your weekend
with the family and friends are becoming more and more popular, for one very
good reason: you enjoy the thrills of a real contest for a few hours, and
then the rest of the weekend can be spent with your family. Not too long
ago, a ham radio friend told me that the four- or six-hour-long contests do
require a lot of skill, especially those that let you select the four- or
six-hour operating period!!!
>
> Item three: FM band Dxing is becoming more and more difficult all over the
world due to the continuos increase of the number of low power local FM
broadcast stations that are receiving licenses from the radio regulating
authorities. Even a 10 watt local with a 6 dB gain antenna will make DX
impossible on its own channel and at least on the first two adjacent
channels, that depending on how close to your location the low power FM
station is.
>
> Nevertheless, dedicated FM broadcast band Dxers are learning some of the
tricks that AM band DXers use, like waiting for off-the-air hours that
station engineers need to do equipment maintenance... By the way, the FM

broadcast band sporadic E DX season has just started, but so far, the openings are few and far apart from each other.
>
> Item four: Homebrewing your radios is a lot of fun, and there is nothing like listening to DX with your homebuilt receiver, or like working DX with your amateur radio rig which you have just finished building. More about homebrew radios later here at the weekend edition of DXers Unlimited, amigos...
>
> And, as always at the end of the show, be ready to copy Arnie Coro's Dxers Unlimited's exclusive and not copyrighted HF plus 6 meters propagation update and forecast. Margarita Delgado is my sound engineer and producer at studio 7, this is Radio Havana Cuba....
>
> Amigos, you are listening to the weekend edition of Dxers Unlimited, and here is our main feature for today: Arnie's advice about homebrewing your radio equipment. First things first... so don't attempt to start your homebrewing with a very sophisticated project, or without having the adequate tools at hand including, of course, your digital multi-meter!
>
> You may perhaps want to start learning how to homebrew your radios by building one of the many kits now available, and as a matter of fact, that is an approach that I do recommend, because kits are an excellent way of learning about electronics.... Unfortunately some of the new generation kits are rather difficult to assemble due to the use of very small electronic components placed too tightly together, thus making your job of putting together the kit a lot harder. Here in Cuba, radio amateurs build a lot of their equipment, and something we all have learned is to homebrew our radios without any attempts to make them miniature sets!!!
>
> Leaving enough space between the resistors, capacitors, integrated circuits, transistors, coils, crystals and other components has proven to be a very good idea, because it is a lot easier to put them together into something that will work, and also because when there is a breakdown, your homebrew set is a lot easier to repair...
>
> Some Cuban amateurs have a second transceiver always ready for emergency communications, and that second radio is typically a version of the JAGUEY solid state double sideband transceiver, running anywhere from 3 to 10 watts, enough to communicate using a Near Vertical Incidence Skywave antenna system on the 80 and 40 meter bands... The homebrew JAGUEY is a quite straightforward design that allows you to upgrade the transceiver to a single side band set if you are able to obtain a single side band filter at a later date...
>
> As a good friend likes to say, when you use a low power double sideband transceiver, no one realizes that you are also transmitting the unwanted sideband, as the other station's radio provides the filtering to pick up just the sideband in use on that specific band... In other words, if I am operating CO2KK with my JAGUEY on 40 meters, other stations using Single

Side Band rigs will only pick up my lower sideband, as their transceivers will just chop away the upper side band when receiving....
>
> Well, as you may realize, homebrewing a low cost double side band transceiver is not only a perfectly feasible project, but also one that will make your station ready to deal with communications emergencies, due to the fact that the JAGUEY needs just 12 volts from a battery to operate, and it draws very little current, even when transmitting. More about the JAGUEY and its most recent improvements in a few seconds, when Dxers Unlimited's weekend edition continues...
>
> You are listening to Radio Havana Cuba, and amigos, if you happen to own a receiver capable of receiving single side band signals, try listening to our 11705 kiloHertz SSB broadcasts in English that start at 0100 UTC and last until 0500 UTC. Again our 11705 kiloHertz SSB is operating using upper sideband at reduced carrier, so that you can zero beat to the residual carrier for perfect reception... For those technically minded, we are running around 20 kiloWatts Peak Envelope Power, or PEP, with -12 dB carrier level, and the antenna is an array of dipoles beaming exactly North of Havana...
>
> And now more about the JAGUEY double side band and CW single amateur band transceiver and its latest version... Among the most recent upgrades are the use of a triple tuned bandpass input filter and attenuator, which makes reception a lot better... Receiver incremental tuning, or RIT, was also added to the basic JAGUEY design, and the CW keying was improved by using a PNP transistor with wave shaping to key the rig...
>
> Also, the NEW JAGUEY has an optional pair of audio filters, one for SSB and the other one for CW, so that the operator may switch from one to the other as required. The NEW JAGUEY also uses a simple but effective transmitter audio compressor that improves the punch of the signal quite a bit. And last but not least, some of the local enthusiasts have now built a very low-cost linear amplifier that uses recycled vacuum tubes to increase the output power of the JAGUEY to anywhere between 20 and 50 Watts...
>
> One very interesting feature of the NEW JAGUEY is that once the newcomer to the amateur radio hobby finds a single sideband filter, the NEW JAGUEY can be readily adapted to be the "tail end" of a single sideband transceiver, so not even one component is lost from the original project. AH, and before I forget, the NEW JAGUEY is a very, very, flexible design because, for example, the receiver audio can be implemented with no less than three different circuits, a straightforward three transistor single ended audio amplifier, a more sophisticated push pull design using discrete components as the first one just mentioned, and the classic JAGUEY receiver audio module that uses a low noise audio transistor coupled to an integrated circuit audio amplifier, the TBA810 or A210 that happens to be plentiful here in Cuba...
>
> Si amigos, yes my friends, oui mes amis... Homebrewing your radio gear is

a lot of fun, and when propagation conditions are not good, then you just plug in the soldering iron, and start building your next project... By the way, I am working now on the NEW JAGUEY PROJECT circuit diagram and operating manual, and as soon as they are both ready, they will be posted at our Dxers Unlimited website for you to download....
>
> One of the outstading features of this unique radio amateur transceiver is the fact that I have included a complete list of parts with sets of values that can be used without the circuit suffering from any degradation.... In other words, you may find right next to each component -- be it a resistor, capacitor, transistor or IC -- a number of options that you can use, making construction a lot easier... As many of you who already have built electronic equipment know very well, the lack of a specific value resistor, for example, can bring the whole project to a standstill, so is was why I spend a lot of time testing each NEW JAGUEY module to learn how the parts values could be changed around without degrading the performance of the transceiver!!!
>
> The NEW JAGUEY receiver chain uses a switched three, four or five position RF input attenuator, followed by a two or three tuned circuit band pass filter, feeding a grounded base or grounded gate RF amplifier stage, that delivers its signal to a double balanced mixer acting as a product detector... audio from the product detector is fed to a low noise audio preamplifier that in turn feeds one of the two audio filters, which in turn feed the audio power amplifier module... The VFO is a very straightforward three transistor module, of which there are three different versions that you can choose from, depending on the parts that you have available. As a matter of fact, newcomers to the amateur radio hobby may build just the receiver part of the NEW JAGUEY and start listening to the 80 or 40 meter bands to pick up CW practice, and then after they obtain their license, they can build the transmitter module!
>
> I'll tell you more about the NEW JAGUEY in our upcoming mid-week edition of Dxers Unlimited next Tuesday and Wednesday UTC days, when I will describe the transmitter chain of the NEW JAGUEY, the Cuban-designed, low-cost double sideband and CW transceiver....
>
> And now, amigos, as always at the end of the show, here is Arnie Coro's Dxers Unlimited's HF plus 6 meters propagation update and forecast:
>
> Solar activity is MOVING UP AGAIN, and both the number of sunspots and solar microwave flux are increasing... Heliosismic data show that we will have from a week to ten more days of higher activity, and don't be surprised if yet another big solar flare erupts during the next few days.
>
> We all hope that the summer sporadic E season will finally take off, too. The best band for amateur radio Dxing during the local daylight hours should be 15 meters, while nightime DX on 20 meters is going to be plentiful for the rest of the summer...

The reason I asked, is of course, I picked one up for a c-note on EBay. It weighs a ton! I have the "A" model which is CCITT, the B model is "Bell" or US Standard, and the C model is no frills. I haven't been able to playwith it yet since I have a broken foot and getting in the workshop is a challenge. (I had one of my kids haul it down.)

I don't want to rain on anyone's parade, but a transmission zero that
close to the passband is undoable even in theory with a preselector.
Anyone interested in infinite passband ripple and an infinite group
delay? A quadrature mixer approach makes more sense and it is relatively
easy to do these days with the integration levels we now have. The other
suggestion of a higher 1st IF is also a good one. IF filters at 109 MHz
or so are readily available at a reasonable cost. RF is a pain anyway.
Buy a rice box. :-)

I should think that it is a matter of attenuation. A good friend of mine is an insurance inspector for a company that underwrites ocean oil platforms. He has used diving gear that has built in radio transceivers. Regular VHF or UHF gear should work if you are transmitting only a few meters or so.

Where? I needed one of those the other day. I ended up building one of Wes Hayward's 110 MHz IF filter designs from his spectrum analyzer project, but I wouldn't have minded finding a commercial part to save the trouble.

The rule of thumb is that radio will penetrate about a wavelength in water,
I don't remember the attenuation then, but it is quite high.

Source record: 44243

Well, it actually works and I have the receiver.

An example of component values used in the Tandberg Huldra 4 (1950-53):
For the 6.9-7.45 MHz band, Cs = 156 pF, and Cp = 270 in parallel with [Cvar in series with 200 pF]. The variable capacitor is also used to tune the medium wave and long wave inputs, so I assume something like 3-400 pF max capacitance. The coil is air-filled and uses silver leads presumably to get high Q. The fixed capcitors have been hand-tuned by grinding off small pieces for fine-tuning, also the coil's end-tap has been soldered manually in place for fine-tuning, indicating that this circuit requires high precision and small tolerances to work. It is used up to and including input frequency 22 MHz.

It shouldn't be too difficult to model in order to find the required Q for this to work with the image frequency notch 910 kHz below the signal frequency.

That's the old "microphone" connector. Looking at some old
catalogs, my guess is the Amphenol Series 75.

What they call a diver radio is usually a wire intercom. Sometimes they
use
wireless but those are an ultrasonic system.
Most of the diving on the rigs is surface supplied so there is no reason
to
not add the communication link on a wire pair in the umbilical.

Source record: 44148

Hi,
I have the C model, with the high-stability time base. It's a superb piece of test equipment (at least the C model is). The built-in tracking generator works wonderfully well for sweeping filters, etc. The A and B model's extra features have no relevance to using the SLM as a receiver, though.
All models make OK receivers. As the other poster noted, the major "feature" you'll deal with is no agc. The frontend is completely broadband; no input filters at all. Sensitivity is poor compared to a "real" communications receiver, but with a decent outdoor antenna, is often adequate. Many folks are starting to acquire these units to use in the QRSS modes at LF. The FCC has just posted info about the possibility of a US ham band at 136kHz becoming more of a reality (the Europeans have had this band for several years now.)
The 3.1kHz filter in this SLM has a very flat passband, with steep skirts; the other filters are broad Gaussian filters--very poor shape factor, but excellent for their intended use in telecommuncations.
Given a choice, I recommend buying the C model, but any of the A,B,C versions will work fine as a receiver, given the comments of above and what others have already noted. And if you got yours for only $100., and if it is functional, then you truly got a good deal. My C model was $500, (the seller didn't know it had the when-new $1000. high-stability time base option), and was in like-new condition, with a current calibration sticker--still a good deal, to me.
Note also these SLM's are not really suited for aural listening to CW signals, as the BFO frequency is high (1.8kHz?), for its intended telecom usage. Of course you can tune in CW, but you'll have to learn to live with its high-pitched tone. I haven't explored the possibility of going inside my unit and trying to change the pitch. My unit's primary usage is as a piece of test equipment on my bench at home; it only sees rare usage as a "receiver". (I'm spoiled by having "real" receivers.)
But friends use theirs regularly for LF usage, feeding the audio output into the computer soundcard and using various QRSS programs to decode the signals. For those applications, the high pitch of the CW note doesn't matter at all.

It is indeed a good recevier even considering you doni¿½t have an AGC but
this is fairly easy to overcome, using the manual entry of the Full
Scale level by pressing: "ENTRY" "FULL SCALE" then using
UP arrow DOWN arrow as wanted, ended by pressing "MEAS CONT"
By offsetting wanted frequency by 1,85kHz, + or - depending of
which sideband you want to hear.
By pressing "COUNTER" you will see the received transmitters actual
frequency.
To my knowledge it is the only receiver that will play
the finale from Beethoveni¿½s 9 symphony... press:
"RECALL" "decimal point" "CNTR FREQ" "8" and wait...

3512. Transistors for Yaesu FT-301 10W final and driver needed!

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-13 03:53:49 UTC
From: Michael Pupeza <mpupeza@sympatico.ca>
Message-ID: <B904B10D.1CBF%mpupeza@sympatico.ca>
Source record: 44154
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment

Hi;
I'm heading to Dayton this week and want to pick up some parts.
My Yaesu FT-301 (Low power) has dropped it's output from 13-15W, down to 2-4W.
I suspect the driver (2SC1589), or 1 (or both) of the S10-12 Finals.
I doubt that the driver will be hard to find under that number, but the S10-12s may be a challenge.
What Motorola, or other Big Brand, might be a substitute?
These are the white ceramic circle with 4 fan flanges, and 2 screw hole tabs at a 45 degree angle to the flanges. A fairly common style, I believe.
Their Output Rating in SSB would probably be 15 - 20 Watts each, with a gain of 10-15 dB, I would guess, on 12V up to 30 MHz.

Any help would be appreciated.
Thanks

A much better two tone oscillator can be
made with two 4-bit shift registers and
8 selected resistors to give extremely low
distortion maybe 80dB down.
G4FQR is writing an article for RadCom
on these.

Its simple. Turn the knob all the way down. Set the meter to read
forward power. Turn the knob up to exactly full scale. Set to
reflected power. Read SWR.

I have one of these meters with the manual somewhere in storage.

==========
I have this unit as well.
1) Put left hand switch in SWR position
2) Pull right hand potmeter/switch to set SWR sensitivity
3) Rotate potmeter mentioned in 2) until meter shows full scale deflection
4) Push switch as mentioned in 2) and read SWR.
5) For power reading switch left hand switch to 250 or 25 (Watts) ,keeping
switch as mentioned in 2)
pushed-in.

You can find a complete circuit diagramme of the HM-2102 ,which will explain
everything ,at :
http://www.circuitarchive.co.uk/heath.htm

Good Luck

All the sources I've been able to find seem to have the same, cheap, ugly rocker switches like at Radio Shack. Nothing that even looks remotely like what is in the average car. While I could slog through a (faraway) junk yard and maybe find something, I'd really like to find a good source to buy from. So far Mouser and similar, custom car/van shops have yielded nothing. Automotive voltage/ low current and 12V backlighting is essential to my application.

Something like

http://www.vehicle-wiring-products.co.uk/VWPweb2000/switch-2/switch-2.html

would be great if available in the US (plus those UK prices are a bit steep!)

thanks,

dnb

If you use compression, it is possible to reduce the size of the image. You will need to do as much of this as possible because any radio signal that will penetrate water to any significant depth will have a very long wavelength and hence a very low frequency. The lower the frequency, the lower the data rate that you can use with it. I would also suspect (but I know very little about VLF (Very Low Frequency) transmissions) that the power required and antenna's length will be major problems for your robot.

Have you ruled out the use of an umbilical cord to carry comms (and possibly power)?

regards,
Mark.

Hi All,
I have a home-brew 20 meters HF rig. My interest is CW. I have a external osillator with paddle etc. Presently I turn-on a switch for CW and press the PTT and use the paddle to work CW. Now I have a computer with the sound card etc. Kindly help me in connecting my rig to the sound card, ofcourse I have to manually press the PTT.
Kindly help me with :-
1. How to connect the rig and sound card ?
2. What software should I use to help me in CW receiving and sending.

Thank you in advance for any info and help.

3527. Re: Terminating HC4066 Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-14 09:45:46 UTC
From: Rodney Green <rodagreen@bigpond.com>
Message-ID: <C15E8.10105$b5.34822@newsfeeds.bigpond.com>
Source record: 44169

I have been using 4066, 4016, and 4053 switch ICs. in mixers for about 20 years or so, and I have found them to be very insensitive to termination impedance. I developed a mixer using 74hc4053 called The Ned Kelly mixer (Ned kelly was an armour wearing bullet proof bush ranger in the 1800s) This was published in Electronics World Jan 1999 P59.

I aklso have a new receiver architecture using these mixers in a number of variations. It is called The Bedford Receiver and was published by the ARRL in QEX magazine Sept/ OCT 1999. These articles could prove useful

A good xtal for CW use in the 80 meter "novice" band.
It is stamped 3724 kHz. -- in my 2-NT it actually was about 3724.5 kHz. Your mileage may vary.

3530. DIYS crystal CB transmitter / receiver ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-14 17:11:42 UTC
From: Torfi <torfitorf@yahoo.com>
Message-ID: <3ce1455c$0$4086$9b622d9e@news.freenet.de>
Source record: 44172

Hello All!

does anybody know of a schematic for simple CB (27MHz, or possibly 49MHz or other "free" or ISM frequencies) transmitter and receiver (seperate) circuits? best would be crystal controlled for frequency stability, micropower (<1W, maybe 100-200mW) would be sufficient. modulation is not very important, should be capable of an audio-bandwidth of about 3-4 kHz.

It's for a robotics/telemetry (moisture sensor) data link I'm working on, that would send short bursts of data every now and then. Should be low-power as the project is short range (house, yard) and I don't want to disturb any other frequency users.

I'm thinking that crystal controlled would be best for me as a digital boy with no HF experience, to build a non-interfering transmitter??

all comments and uncommented links welcome!

regards,

Torfi

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday May 19th 2002
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

SEASON PASS + Advance Discounts

A sellers discount season pass is available which
offers a 33% discount. See the advanced registration
form below for full seller info.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Message-ID: <3CE1BB2F.2010508@charter.net>
Source record: 44179

what is the difference between the dentron

models CM-1 and CM-2 tuned input boxes?
What i have is a clipperton L i have replaced the caps they are a bit
taller. the bill edwards tuned input internal board will not lay flat in
there now.
I am in sorta of a bind. not much room in the amp to move it around.
Can't put it over the p/s or in the rf compartment. only verticial left
right in front of the meters.
which if installed this way would make it hard to tune the slugs if need be.
anyone have any suggestions?
thanks chris NI4L

Source record: 44181

This is the 6 M AM transceiver spotlighted by the IA QRP club a year or so ago. This is a rig designed by Rick Littlefield originally called the Nor'easter and published in Communications Quarterly. I have the board, the pots, a used CB modulation transformer, the modulator chip, the crystal filter (the good one), and the coil form. I am also including all documentation, addendums (some items in color), and a copy of the original article. I'll sell it for $20 shipped priority mail (lower 48). This is a really neat project. I've just never had the gumption to get it finished.

I have the two chip set that allows Kenwood TS440, TS-940, TS-811 and TS-711 transceivers and the R-5000 receiver (I believe). I bought them because they were advertised as a IF-10C interface kit and these are NOT an IF-10C interface (that's a board). I'm asking $40 (what I paid) but I'll take best offers. (BTW, the installtion instructions are in the owners manual - not included) Or if you had an IF-10C that you wanted to trade me I'd sure take that!

3540. Looking for a Low Noise Inverter

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-15 05:44:38 UTC
From: "Jim Hill, w6ivw" <XXslimjimis@cox.net>
Message-ID: <r4t3eu8o7m4hpnlrhosm8l8msh0fc11rgc@4ax.com>
Source record: 44183

I'm looking for a 12-120V inverter that creates minimal AM radio noise. I collect old radios, and would like to take some with me when using my RV on trips. Ideally, I would like an inverter that would not be heard when I connect a radio, tune around 540 kHz where no station is heard, and turn up the volume. Modern inverters seem to have high frequency switching power supplies that generate plenty of RF. Any suggestions?

You are going to have to go with one of the 'true sine wave' inverters.
They are much more expensive, depending on the power required, but they
make much less noise.

http://www.homepower.com/
Is a web site that should have links and references that will help you
find something.

I can dig through some of my catalogs if you can't find anything.

It may be easier to build a sine oscillator/amplifier and then use a transformer. If you don't want to screw around building a wien bridge, use a square wave oscillator and put an active low pass filter (you'll need 3 or 4 sections) on the output. You don't need a low distortion amplifier, just make sure there's no DC on the output. Note, the transformers in tube equipment work fine at 60Hz, but you don't need to run the oscillator at such a low frequency for this application, and is probably irrelevant if you are running the old "hot chasis" am radios. A couple years ago I posted on this bb the fact that we used McIntosh amps with 6L6's to run experiments in the solid state physics lab where we had to be completely divorced from the AC mains. Lastly, Linear Technology has some low noise switcher chips which would work well in in a push-pull configuration. Search on their website. (www.linear.com)

3547. Wide band Radio Transceiver Board

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-15 19:56:56 UTC
From: smishra@smishra.com
Message-ID: <8787ae79.0205151156.f6a0df3@posting.google.com>
Source record: 44189

Hello:
Is there a commercial wideband RF transceiver board which can be
controlled by a host to set its

1. Base frequency
2. Passband frequency width (upto 1 MHz if possible)

I am thinking of experimenting with RF links using DSP. I am currently
thinking of building something like

Antenna <--> Transceiver Board <--> A/D,D/A <--> DSP
| | |
|_____|_____|
HOST

I am an EE so I have ready access to and knowledge of DSP and A/D and
D/A boards and host boards. However I have not yet been able to
identify a transceiver board that would fit the requirement.

I do not want to build my own board since my interest is in playing
with software.

Thanks
Sanjay

Should do fine. I wouldn't overdrive the input though. A transformer isn't needed. At least I don't use one, and it works fine.

tnx.
this is what I expected, but it seems often to be lot of experience
presented by hams which is not based in any facts, so you may wonder
what is the secret in 50 ohm terminations. In my opinion 200 ohm is
better for RF, and for my purpose - on 136kHz - I don't see the need
to use a diplexer for proper termination on 100MHz or above

So I am pleased to learn about your experience regarding termination.
A friend who is experimenting with this says he cannot note any
intermodulation products provided the peak-to peak signal is lower
than the supply voltage, so it seems difficult to overload the mixer.,
it would mean a signal level of +15dBm on the antenna, but no signals
below few MHz has be found to be stronger than -50dBm on the active
antenna used for LF

Don't worry about matching the impedance. When you have a source such as a 8 ohm speaker and are feeding into a sound card with an input impedance that is way over 10 times higher there is no loading and not much distortion. You just have to have enough driving power which the sound card has plenty of. Same as for the input to the transmitter. You may have much more drive than needed and you may need to insert about a 10K to 100k resistor in series with the wire comming from the audio card and then put a 1 K resistor to ground to cut out some of the drive.

Does anyone know what parameters usually apply in matching RF power FETs?
Do they normally match for more than just Gfs?

Source record: 44194

I would expect 200 ohms would be a good range although there are
tradeoffs.

I would make sure to match the output of the Antenna to the same
impedance. The reasoning is, the ON resistance of a 4066 is quite a few
ohms, and so the insertion loss in a 200 ohm system will be lower.

You do lose a little of the maximum input level, due to the impedance
transform raising the RF input voltage.

As for terminating the LO frequencies at the mixer output with a diplexer,
I wouldn't worry too much about it. The internal isolation of the 4066 is
good enough that the amount of LO energy on the output can reflect back into
the switch and not degrade the performance very much at your frequencies.

So, the tradeoff choice is, lower conversion loss/lower intermod point
with 200 ohms or higher insertion loss/higher intermod point with 50 ohms.

You can more or less predict the distortion point, since the RF will clip
as you approach VCC. Obviously the switch has to be DC biased to half of
VCC for maximum dynamic range.

I'd supply DC on the output side of the mixer, and AC couple the input.
The input will go to 1/2 VCC as the switches turn on. Leaving the input
floating to DC will minimize the tenancy for the DC level to change as the
switches turn on and off.

Given the noise level at the VLF frequencies you want to use, I'd be
inclined to go with 50 ohms since you can afford the conversion loss....

Receiving is no problem. Use the speaker out from the rig to the "line in" on the sound card. You can adjust the volume withing the computer. Also you can adjust the volume from the rig. To the rig, the main thing is to just not overdrive the mike input, and I always check the polarity. I want the ground side on the computer card going to the ground side on the rig. On the 706 I've been using I rigged up a set of resisters and a pot to adjust the level. I can also adjust within windows also. I might add... If your card only has a "mike" input and no line input, you may need to lower the gain to the sound card. A "mike in" is more sensitive than a "line in". But most all cards made in the last few years have a line in. MK

Hi Jan-Martin and others,

as far as I have not enough expirance with a 4066 mixer, but
what about the adg711-712-713 ic from AD.
The ON resistance is between 4 to 8 ohm depending on the
supply voltage.
The ic is much more expansiv, but is suitable up to 200MHz.
Would be great to find someone to make some test with it.

The FST 3125 from Fairchild, Texas Instruments, Perricom and others exhibits under 4 ohms of Rdss, works to somewhere well above 30 MHz, has the switch drivers on board, and an Ip3 of above +42 dBm, (With square wave LO) . It costs under a buck in single quantities from DigiKey. (TI is $1.02). I've measured under 5 dB conversion loss in the "H" mode configuration with both MCL TT4:1A transformers at 200 ohms and MCL T1:1T's at 50 ohms, both at 20 meters. Slightly more using T4:1's. It all gets better (But not a lot) when you raise Vdd from 5 volts to 7 volts, max ratings. Available in both SSOP and TSSOP.

Hallo Harold and the world,

is such a switch ic suitable for qrp (means power consumption)
and also suitable for direct conversion to audio by a pair of
this ic (I and Q chanal) to avoid the sideband filter?
Have anybody made experience with this technique?

Would be great to get some hints what to pay attention for when
designing such a rx.

Markus

Hi,

You may order your new QSL-cards from UX5UO:
Almost any type of QSL cards is available today.

Price of 1000 QSL-cards (including handling and mailing fee) is:
"Simple" (single colour one side 150 g/sq.m paper) cards - 22 USD*
"Advanced" (single colour one side 200 g/sq.m paper) cards - 26 USD
"Middle" (two colours one side 200 g/sq.m paper) cards - 32 USD
"Middle2" (two colours double sided 200 g/sq.m paper) cards - 38 USD
"Business" (200 g/sq.m paper double sided matt photo) cards - 44 USD
"Luxury" (200 g/sq.m paper double sided glossy photo) cards - 56 USD

Discount for ordering 3000 and more cards as well.
500 cards is possible as exception. Special discount for DX stations.

Cards will be printed within 3-4 weeks upon receiving order and payment
for all types of cards except picture cards (within 2 months for photo
cards).

Send your order (photos, rough design, text data etc) via mail:

Thank you Mark. I am planning to use a creative sound card with
windows 95 and it has the "line in" input, so no problem on that. I
will take care of the polarity also. If possible kindly give me your
setup of the resistors and the pot, so that I can duplicate it here in
my setup. My basic fear is that my rig is a homebrew with 48V at the
final pumping out 25W and I don't want to blow-up things. Also my main
concern is receiving CW, I can manage sending at 10WPM.

thanks again

> this ic (I and Q chanal) to avoid the sideband filter?
> Have anybody made experience with this technique?

I don't know the power consumption. Not being green or into QRP, I've never measured it. My board layout includes 3 digital 74AC IC's in a variable divider chain and all 4 chips draw 60-100 mA at 5 volts, depending on LO frequency. (110 mA at 150 MHz, about the upper limit of AC logic). I use the 3125 for RF mixing to an RF IF frequency. I have used the FST 3253 (Only takes one for both I and Q) in my construct of Rod Greens Bedford receiver. As far as either of us know, it was the first one built. (After his, and his great article in QEX) Works fine. I use the Burr Brown INA 103 op-amp amplifiers post detection ahead of the phasing networks.
>
> Would be great to get some hints what to pay attention for when
> designing such a rx.

Layout Symmetry!!! And square wave LO. And a steady hand if using the TSSOP package with it's 0.025 leads!

Has anyone come up with a way to make the MD 100 work with a Yahoo FT990? There is one mod but it requires a butcher job inside the base of the mike. I tried dropping the voltage from the remote from 13.8 vdc to 5 vdc before the mike and it did not work, any ideas??

3571. Re: Terminating HC4066 Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-18 01:16:58 UTC
From: la8ak.xnd@online.no
Message-ID: <3ce5a68a.190699247@news.online.no>
Source record: 44112

Tnx,

now I've built the new converter using 74HC4066 with 10V supply. Use a
TIS88 as buffer to 60kHz two stage BPF (4.5mH coils) and S042P as
mixer up to 3627kHz to be fed into Yaesu FT-902. An old 4069UBE is
used as buffer for the 195-198kHz VFO

Lowest CW signal level easily tuned is -120dBm (75 ohm) and lowest
signal level heard when you know it is there is -126dBm, so the mixer
seem reasonable well without RF stage.

The idea for input circuit (although it seems to be somewhat wrong as
it was used on 7MHz) is found at http://home.snafu.de/graff/sbt40.pdf,
so I use 1.5mH high-Q coils with capacitor values for the 2nd circuit
are 1137pF, 10nF + 10nF (no trimmer capacitor).

A xtal filter described by SM5BSZ was planned, but I didn't succeed
building it for 60kHz, so in the meantime LC-circuit is used, I hope
to visit some friends in the summer holiday to get some help in
trimming it, it isn't so easy when everybody who could help is at
least 200 miles away or in another country, hi.

didn't see any schematics for the SSB project so I looked at the DSB
project instead. Looks like most of the schematics are found in other
books.
As I just finished a project using 74HC4066, I would believe this
device would simplify such receiver very much, particularly with 500
ohm on the mixer run at 10V DC. Suppose at grounded gate amplifier has
not much gain and a HC4066 mixer has very low loss, so it might have
higher audio output than the homebrew ring-mixer with grounded gate RF
amplifier, see http://home.snafu.de/graff/sbt40.pdf

3587. Old messages this NG

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-19 09:04:14 UTC
From: Frank Dinger <gm0csz.kn6wh@ntlworld.com>
Message-ID: <cVJF8.869$Nh.39175@newsfep1-win.server.ntli.net>
Source record: 44129

Using MS Outlook Express I monitor this NG by downloading ALL NEW messages ONLY, removing them from my system when read.
Up to early this month each time I did receive the NEW messages ONLY as specified.
However since approx 2 weeks the system each time also downloads a few dated messages which were downloaded before and subsequently read and deleted .

Today 19 May 02 I again received a few messages dated 12 & 13 May I had read before and deleted.

Is this due to my system or do all readers of this NG have this problem?

TIA for response

Frank gm0csz.kn6wh@ntlworld.com

Frank,
Sometimes news servers may hiccup and will download older messages
and present them as new. This is a news server issue and has nothing to
do with OE.

I had a similar experience some time ago, it was a problem with the ISP's
newsserver. At this point in time, don't worry about your system, but do
notify your ISP.

I don't have that problem with Agent.

Danny

Frank
I've been getting the same problem here and wondering if it was a problem
with my machine but you've solved it - we're both using NTL.
Time for a complaint.

Message-ID: <qXQF8.75799$ja.19973433@news02.optonline.net>
Source record: 44135

A few days ago i came across a website that had different homebrewed radios and such. the most interesting thing i saw was a cavity tuned to two meters, and the author used it as a near field reciever. The contraption was built out of a coffee can and had a screw type device at the top to tune it. The only "electronics" was a 1N34 diode. Has anyone else seen something like this or know about this website. Its not really sensitive, the author used it to monitor his repeater. thanks in advance

Same problem here Frank. Only I'm using Turnpike, not Outlook. And it's
not just this newsgroup, but several others as well.

But we are both using NTL......

Thanks for the many responses on my above referred message.
Indeed it appears to be the ISP (NTLWorld) as also reported by others
If the problem continues I'll report / complain to my ISP
BTW the last 2 downloads were OK.

Tnx agn

3598. FS: Power transformers

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-19 22:18:09 UTC
From: Terry Perdue <k8tp@home.com>
Message-ID: <BwVF8.41291$L76.41078@rwcrnsc53>
Source record: 44140

(For anyone who tried to contact me via email by responding to the earlier post, please try again; it will work now. (Bill - your phone is off-hook.)

I have three new power transformers that would be ideal for a solid state kilowatt RF amp, high power audio amp or monster bench supply. These are real beauties, but very heavy - probably 30-35 pounds each - so shipping may be costly. Located in Seattle area. Specs are as follows:

(Primaries are the same on all three - dual 100/115V (200/230V), 50/60Hz.)

Xfmr #1:

One 55V secondary, tapped at 4V, 40V, 45V and 50V. Rated at 250A peak (6% duty cycle), using a bridge and 150,000 uF cap.

Xfmr #2:

Secondary #1: 50V, tapped at 30V, 40V and 45V. Current rating not known, but substantial.
Secondary #2: 28V center-tapped at 8A continuous, 50A peak (20% duty cycle), using a bridge and 50,000 uF cap.

Xfmr #3:

One 55V secondary, tapped at 4V, 36V, 40V, 45V and 50V. Rated at 100A peak (20% duty cycle) using bridge and 50,000 uF cap.

If interested in any of these, and able to pick up or willing to pay shipping, contact me, and we'll work an easy deal. Interested in trades. Can email pictures.

3607. Minimum Loss Pad

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-20 18:43:35 UTC
From: la8ak.xnd@online.no
Message-ID: <3ce93c96.425755382@news.online.no>
Source record: 44049

Have to measure RF transformer losses, but my measuring apparatus have different impedance, so I need a minimum loss pad. But unfortunately I cannot find where I have seen the construction (thought I had lot of copies a few years ago!).

Would be pleased if somebody could tell me the formula to calculate resistor values and attenuation. In the actual case I am testing 50ohm unbalanced to 200ohm balanced, or 75 to 300 ohm, and need a pad between 200 and 120 ohm balanced, and between 300 and 120 ohm.

hope to hr fm u sn

Source record: 44050

I don't know about the particular project you've been looking at, but
can relate my own experiences. It sounds like the project you looked
at may be using the coffee can as an antenna as well as a resonator;
you didn't mention if there's a connector/lead from an external
antenna or not.

Anyway, the design I've played with is a resonator...typically a
helical resonator a bit more than an inch in diameter...with the
signal coupled lightly in at the bottom, to maintain high loaded Q.
The detector taps up quite a ways, and so long as the signal level is
low, the detector presents a high enough resistive component of load
that the Q remains high. I'll normally send the detected signal off
to a chopper-stabilized amplifier with very low input bias current,
arranged as a log amp, but the Analog Devices log RF detector ICs
should work, too, instead of the diode detector. I've been using an
Agilent zero-bias Schottky detector diode, and can see input signals
down in the few-mircovolt range with it. Then the high Q of the
resonator becomes important, so you don't "listen to" a whole bunch of
stations all at once. Two coupled resonators helps even more...it's
feasible to get loaded Q's of around 1000, maybe a bit more, so you
can have bandwidths less than 100kHz. That's not exactly "narrowband"
but a lot better than something several MHz wide. It's interesting to
note that with isotropic transmitting and receiving antennas in space,
with a 5-watt 2-meter transmitter, you get 50 microvolts in 50 ohms at
just over 50 kilometers...and I can definitely "see" 50 microvolts of
RF with this sort of setup.

BTW, what are you looking to accomplish?

Cheers,
Tom

Scientists on tropical island using found materials. Also kite. Should be stimulating entertainment with Kate Humble supervising. Spark tx should be ok, but how about the crystal for rx?

Not as difficult as it sounds... Try a decent silica-based
valve-grinding paste.

| Program name: MATCHPAD.exe Author: R.J.Edwards G4FGQ (C) 6th May 2000
|
| DESIGN OF RESISTIVE MATCHING-PADS & ATTENUATORS
|
| An assymetrical 3-resistor T or Pi network has input and output image imped-
| ances I1 and I2 respectively. When the output is terminated with its image I2
| the input impedance is I1, and vice-versa. For an ordinary symetrical atten-
| uator both I1 and I2 are equal to the pad's characteristic impedance, Zo.
|
| When I1 is equal to a source resistance and I2 is equal to a load resistance
|an impedance match occurs simultaneously at both input and output terminals.
|If such a condition exists the loss due to the matchpad in dBs cannot be less
|than the minimum value determined in a complicated manner by the ratio I1/I2.

| A pad so designed is known as a minimum-loss matching pad. A resistor in the
|T-network becomes a short circuit. A resistor in the Pi-network becomes open circuit.
|Both T and Pi reduce to the same minimum-loss L-section. All designs for matching
|pads with attenuation less than the minimum result in some comp-
| onents having non-realisable negative resistance values.

| This program computes the mismatch loss without a matching pad relative to
|maximum power available when load ohms = source ohms, the minimum matched
|loss for given values of source and load, and T and Pi-pad resistor values.

Yes, but when it is requested to enter
source impedance
terminating impedance
and attenuation

I don't know the attenuation, it is what I wish to calculate, tried
some different figures and got result with negative resistances

I actually posted this in a reply message in a thread, but thought I'd make a more general announcement as an invitation to everyone.

I just finished my first ham radio page. Pretty simple stuff, but some nice links to some of my favorite QRP and Homebew sites amongst other stuff (a ULS link, and some other good ham radio pages on CW). Included also is a bit of my ham history (i'm a new ham, so it's a short history! LOL)

Let me know what you think!

Jason - N6WWW - November Six World Wide Web

And for those on IRLP, you can catch me on Node 396

(I'm actually monitoring right now for those hanging out online
It's 4:25pm Pacific 5/20/02 right now)

3614. Return of the Windom

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-21 03:34:32 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <accf88$76p$4@knossos.btinternet.com>
Source record: 44056

New Program: WINDOM2.exe

The original Windom (1929) antenna has now fallen into the antique category. It is a simple 1/2-wave horizontal dipole fed over a single-wire transmission line of no particular length except that it has to come down near to ground level to be fed against ground just like all ground-mounted verticals. The trick of using a single wire feedline is made possible by tapping the line into the dipole at a short distance off-centre.

By tapping at the right place the vertical feedline can be approximately Zo-matched. The SWR can be reduced to 1:1 yet the feedline will still radiate. But since this fills in the nulls in the dipole's radiation pattern it will always be welcome.

As just described it was originally used as a one-frequency antenna. The main reason being that in the early days transmitters were capable of transmitting on only one frequency. It might have had something to do with steam-driven LF alternators.

However, in these days of tubes and transistors, it turns out the Windom is a multi-function, multi-frequency, multi-band antenna. Provided its height plus the length of the longest 'half' of the dipole is longer than about 1/6th wavelength at the lowest frequency of operation it has a consistently high radiating efficiency.

Its relative high base feedpoint resistance means that a very extensive gound electrode system is not necessary. But for multi-band operation a matching network is always needed. The program calculates the L and C values of an L-matching network. When a single series tuning component is all that's needed the program calculates that too. The loss in the L-network is taken into account when calculating overall efficiency. A coil Q of 200 is assumed.

A table of loss resistance values of the ground connection for various numbers and lengths of radials is included in the notes.

The antenna can be changed from Inverted-L, to Dipole, then to a T-antenna by lowering the dipole and sliding the tap along the wire. This will change input impedances and radiation patterns. Scope for experiments?

This deceptively simple antenna deserves greater interest and popularity - for both novices and old timers.

Download program WINDOM2 in a few seconds. See what makes it tick. About 51 K-bytes. No unzipping inconvenience.

3615. Re: Minimum Loss Pad

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-21 04:37:59 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <acciv6imd1@helle.btinternet.com>
Source record: 44057

(1) Enter source resistance.
(2) Enter load resistance.
(3) Initially enter any number of dBs you fancy.

A MESSAGE APPEARS ON THE SCREEN WHICH TELLS YOU WHAT THE MINIMUM LOSS
ACTUALLY IS BETWEEN THESE TWO RESISTORS.

For 50 and 150 ohms is it 9.9 dB ? (I forget)

(4) You then enter the value of the (minimum) loss back into the program
and it will tell you the values of the TWO resistors which make up the T and
Pi minimum loss pads.

The trouble is, if you don't know to work it out from first principles with
pencil and paper, its very dangerous to try using a computer. ;o)

OK ?

Yours Reg.

Many thanks for this info Harold.
Would like to make my own experience, but by the way
did you ever try a DDS IC for the LO for example
the ad9854 (10bit DAC). This chip provide tow outputs,
one for I and one for Q channel.
I was told, that it's not so easy to make the low pass
filter following the DDS IC to reduce the frequencies
above clock/2 when taking the phase into account especially
when trying to construct a I&Q-DC-Rx. But this is another story.

I've used a pair of 9851's (Without the 6X PLL, too much jitter in that for the application) in a VNA. Fine for that purpose, but I wouldn't want to use a straight DDS for a LO without PLLing it to a VCO to kill the spurs. I sure wouldn't want my neighbor at the foot of the hill to be using one at any power level above a watt or two, his phase noise at a couple hundred KHz is bad enough now.

You can make a perfect quadrature output with a pair of 7474's, but it cuts the frequency by four. If you can live with that, it doesn't do a lot for the spurs, but cuts any LO phase noise by 12 dB. You get automatic high level (~+17) dBm square wave LO out of them as well.

I don't know if anyone has seen the website I'm looking for (I hope they have), but I've lost the link so I cant give it to anyone either.
Hoping someone can help me with the web address.

The website is about a bloke in America (maybe Canada I can't remember). He is an amateur that lives in a zone where the power delivery isn't fantastic. To combat this he set up a car battery in a battery box with a volt meter and a cigarette lighter socket built in (as well as big posts for his radio equipment). Apparently this wasn't good enough so he linked up a solar system to it as well. There were a couple of other attachments also.

Hoping someone can help me out with the address for it.

Thanks in advance,

Brian.
Sydney Australia.

Brian, you would be better off using a battery made for supplying a relatively small amount of current for a longer time. A car battery is optimized to supply a huge amount of current (100 to 200 amps) for a short time in order to turn the starter motor. When the car is running, its electrical needs are supplied by the alternator powered by the engine. Gel cells are really what you want. They are sold for computer room uninterruptable power supplies (UPS) and camper vehicle use. Perhaps you can get them from a computer service company or just buy a couple of new ones. The gel cell have a charging power requirement similar to Nimh batteries and the charge control chips for Nimhs work well for gel cells. Do a web search for "gel cells" and you will get all you need! Also, do a web search for "Luke Enriquez". He is an Australian ham and engineer who has a nice design for a gel cell maintenance system.

Hi there,

If you've programmed a Motorola People Finder in the past and can remember some of the basics, I'd like to pick your brain with some questions.

I have an NOS unit here (purchased second hand), with most of the information. The internal radio is a modified GP-300 rf package on a board. I'd like to ask some programming questions about it.

I'd also like to know if you've used an Alpha Mate with it and or the external VDT or smart term. I'm setting up a basic paging system and hope this unit will work for my needs.

I have what I think is all the proper software and connections... I might have a question or two about the various programs you might have used.

thanks much
skipp
skipp@pilot.ucdavis.edu

Please, no spam or unsolicited Emails... thank you

Source record: 44070

Hallo Harold,

I have read some articles in the German ham magazine Funkamateur
about this concept with the pair of 2xD-FF (74x74) for generating
clock for a 74HCT4066 Mixer for a I and Q channel DC-RX.
I have made some scanned copies, if you are keen on it, I can
mail them as a attachment to you.
In the case someone use a DDS like the AD9854/9857 for the switching
of the 4066 he avoid it to make different LO's with four times higher
frequencies for the different sw-bands.
When using the ad9854/57 you get a better phase noise (about 80 dB SFDR)
because of the 12/14bit DAC.
When someone avoid to use the internal multiplier of the DDS chip like
you
mentioned before and take a stable oscillator for clocking the DDS he
could
achieve a good performance over a wide range of frequencies.
I have not tried it before but this will be may next fovored project in
the future.

The late Tom Douglas who held the call G3BA was a Prisoner of the Japs.
He fashioned a makeshift 'crystal' receiver - IIRC a razor blade was
one of the principal components.

Hi Jan-Martin,

Reg suggests his program, them cautions that it would be good to know how to work it out yourself before trusting the computer. To that end, consider that, for example, to go between 200 ohms and 120 ohms, (or Rhigh and Rlow in general) you need a series resistor (say Rseries) between the two, and a shunt resistor across the Rlow side (say Rshunt). (For balanced, you just split the Rseries into two, one on each side, of course.) Then you set up two equations to solve for Rseries and Rshunt:
Rhigh = Rseries + (Rlow||Rshunt)
Rlow = Rshunt || (Rseries+Rhigh)
The algebraic manipulations to reduce those to something you can plug Rhigh and Rlow into to solve for Rshunt and then Rseries are a bit tedious, but not really difficult. Note that you can solve the first for Rseries, and then plug that into the second, so it becomes a single equation in one unknown; it is, however, (a very simple) quadratic. From the resistor values which result, the attenuation should be apparent, I think. (Just a voltage divider of Rseries and (Rhigh-Rseries) going one way, and an equivalent current divider going the other.) (As a check, it looks like -8.6938dB to me, for the 200:120 case, -12.9408dB for the 300:120 case.)

Cheers,
Tom

in my circuit CD4069UBE draws only 10mA. I wasn't sure how much
voltage was safe to use with such inverter in linear mode, so I
reduced the voltage with a 220 ohm resistor from 12V. Suppose it is
the first limiter which draw current and the next two inverter stages
of CD4069UBEand HC4066 draw very little current, so I really don't
understand the 23dBm LO level you mention.. LO frequency is 196kHz

Hello,

I have several of this antique globe shape German triode in stock. It is directly heated, an European 4-pin base and about 12W anode dissipation. The heater is 3.8V 0.72A, u=17, S = 3.0mA/V Max. anode voltage is 400V.The valves are NOS, but the boxes are mostly in bad shape. You will find a picture at my web site. www.demostenes.no
Just search for RS 242.
Please contact me if you are interested.

Regards,

Arnold Goks�yr
DEMOSTENES - N6899 Balestrand, Norway

From: oldbooks78@aol.com
Message-ID: <20020521175351.20039.00000159@mb-mv.aol.com>
Source record: 44078

I currently have for sale a variety of older radio-related books. Postage is $2 for the first book, and $1 for each additional item (Media Mail within the US, at cost elsewhere). The books are:

"The Radio Amateur's Handbook, The Standard Manual of Amateur Radio Communication" 47th Edition, published by the American Radio Relay League, 1970. The 600+ page softbound book is in good condition. There is a 4 inch tear along the rear cover spine, and a few bent page tips, and a brown magic marker smudge on the page ends. Internals are clean with no page tears or pen marks, and a strong binding. A good vintage reading copy. Available for $6.

Terman, Frederick Emmons "Radio Engineering" published by McGraw-Hill, 1947. Third edition. The 969 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name and address inside the front cover. Strong binding and very clean covers. A thorough treatment of radio and communications including ultra-high-frequency and microwave techniques. A very nice copy. Available for $15.

"Reference Data for Radio Engineers" Second Edition, published by the Federal Telephone and Radio Corporation in 1947. The 322 page hardbound book is in good+ condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover. "The present edition has been greatly enlarged and a subject index included. Chapters on transformers and room acoutics have been added. The material on radio propagatiion and radio noise has been revised. The data on cathode-ray tubes have been considerably expanded." Available for $9.

Everitt, William Littell "Communication Engineering" published by McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the science of the radio. Available for $9.

Measurements Development Laboratory of the Sperry Gyroscope Company, "Microwave Transmission Design Data" published by the Sperry Gyroscope Company, 1944. Publication No. 23-80. The 215 page hardbound book is in very good condition, clean with no page tears or pen marks, and a strong binding. Originally issued during WWII as a "confidential" document. Chapter topics include General formulae for concentric lines; Attenuation in concentric lines; Reflections and impedance matching; General formulae for wave guides; Attenuation in wave guides; Reflections and impedance matching in wave guides; Wave guide tees and bends; Wave guides filled with dielectric material; Dielectric material: Cavity resonators; and Measurement techniques. A neat early book on ultra-high frequency radio waves. Available for $7.

Massey, H.S.W. and R.L.F. Boyd "The Upper Atmosphere" published by Hutchinson of London, 1958. The 333 page hardbound book is in good+ condition. It is an ex-library copy from a corporate library, with a card pouch inside the rear cover, and the usual stamps and stickers. The rear inside hinge is split, but the cover is securely attached. Otherwise in decent condition. Available for $6.

Hall, Gerald L. (editor) "The ARRL Antenna Compendium (Vol. 3)" published in Newington, CT, U.S.A.: American Radio Relay League, Incorporated, 1992. ISBN: 0872594017 The 236 page softbound book is in fine condition, fresh and clean inside and out. Lots of useful information on radio antennas. Available for $7.

Erwin, David G4LQ1 "HF Antenna Collection" published by the Radio Society of Great Britain, 1994. ISBN 1872309089 The 233 page softbound book is in fine condition, fresh and clean inside and out. Lots of useful information on radio antennas. Available for $7.

If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

Don't they have gennies down there? I live in a part of the third world called New Jersey and our electric company, once known as General Public Utilities (aka three mile island) is notable for outages. Some joke on us, they got taken over by First Energy which discovered holes in the Davis Besse nuclear reactor (used to be Cleveland Electric). Ergo hoc, propter hoc I have two generators for power outages.

I used a pair of 9851s phased 90 degrees apart to run one of my DC quadrature detectors. A pair of 9851's draw much less power than a single 9854, and it allowed me to run at 1x on both 9851s, but still generate the two bit clocking sequence that you are discussing with a 7474.

However, my experience was that the 9851's generated a fair number of very narrow birdie spurs. I was stepping the 9851's at a 0.014 Hz resolution for continuos tuning. If a larger step size like 25 or 50 Hz were used, most of these birdies would be skipped right over.

Those 10-bit DDS parts are junk (IMNSHO). Fine for a BFO, but I
wouldn't use them for anything else.... certainly not to drive any mixer
that doesn't have a sharp filter in front of it.

The 9852/9854 generation is much better, and they're not really that
much harder to use.

Probably so, but a car battery will run the station for an awfully long time. Out here in the wilds of Michigan it's fairly common practice to use a car battery and a trickle charger. Combined they cost less than a "proper" supply, and even the worst ice storm rarely takes out the power long enough to drain the battery.

Good heavens, you never made a "foxhole radio" when you were a Boy Scout? A razor blade, preferably a little rusty, and a pencil lead. They used to have blades that had bluing on them like a gun ... if I recall, they worked extremely well, or maybe not at all, now I'm not so sure. I was probably 8 or 9 at the time.

Hi Fellas;
I have for SALE:
1)- bag of 20 various I.F. Cans, millers & other brands, 10.7FM, 440-475kc, 250-275 air core, 455 Discriminator, etc
Price is $22ppd, See pic>>
http://www.myradioroom.com/20ifcans.jpg

2)- 42 Various Value Wire Wound Power resistors, Price is $15.00ppd, See pic>>
http://www.myradioroom.com/42powerresistors.jpg

3)- 230 Wire Wound Chokes, various values such as .9, .3, .1, 1.4, .4 Uh. About 50% have adjustable cores.
Price is $23.00ppd, see pic>>
http://www.myradioroom.com/230-wwchokes.jpg

Don't know the site but all you need you will find in yachts chandlery catalogues. We live permanently on 12 v batteries. Solar / wind / additional engine alternator / towed rotator if we could get 12v from rubbing two sticks togethere we would do it.

3646. Re: Terminating HC4066 Mixer

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-22 03:14:13 UTC
From: Dan Tayloe <dtayloe@cox.net>
Message-ID: <3CEB0D05.7810BEAC@cox.net>
Source record: 44088

Actually the extra two bits (12 vs 10) for the 9854 vs the 9851 don't seem to gain it very much, at least from the advertised specifications. Narrow band spurs are 80 to 90 db down for both parts (wideband ~ 50 db down), with the 9854 being only a couple db better than the 9851.

My experience showed me that the 9851 was not a good part for direct use as a VFO for a high performance radio, and the 9854 is at best a few db better (from the specs). I understand that they can be cleaned up significantly by using it as a reference to a VCO and have seen much exciting work on that topic on this list.

On the other hand, the even less complex 9835 does well in the DSW series QRP rigs because it provides a simple, stable frequency source and not everyone needs the ultimate experience in high end receiver performance.

I myself am trying to pursue very high end receiver performance with very low end current drain and DDSs don't provide what I am looking for.

One good thing I noticed when using the dual 9851s, the quadrature drive I got from that arrangement was superior to using a pair of very fast 74LCX74 flip-flops clocked at 4x, even when both flip-flops were driven simultaneously from the same 4x clock signal. When using the flip-flop approach, the DC quadrature balanced shifted from band to band, making it necessary to provide a balance adjust for the different bands to get the best DC image rejection. This was not necessary when using the dual 9851s as the balance was rock solid from 1.8 to 30 MHz.

The blue blades didn't work well.. the "bluing" was a sort of plastic
coating that kept the pencil lead (or safety pin) from conducting.

Foxhole radios are about the very simplest radio receiver possible. They can be built from any two dissimilar metals and a length of wire and a crystal earphone. During WWII, the parts of choice were a safety razor blade and a either a pencil lead or safety pin. The blade was mounted to a piece of wood as was the safety pin. The pin was mounted so that the point end could be moved around the surface of the blade to find the most sensitive detection point. The length of wire was connected to the blade, one side of the earphone was connected to the safety pin. The other side of the earphone was connected to a ground point. These radios had neither selectivity (they picked up whatever was closest) nor sensitivity. They were best suited to receiving CW (Morse) signals, although they did receive AM signals as well. Alternatively, a high impedence dynamic earphone, popular at that time, could also be used.

The only CW they could pick up would be MCW which is AM.

Hey Hams,

On my ham page I added a really slick message board that some of you may enjoy. If anything, it's fun to look at the really neat interface.

Anyway, I tossed a couple of messages on it. It's there for all to enjoy.

http://n6www.cjb.net

Click on Message Board near the top.

Let me know if there are any other discussion sections you'd like me to add to the page.

I also have liks to ULS, IRLP, Homebrew, QRP, and ham training sites for those interested in seeing some of the fun places I've found along the way.

Also, I'm hanging out on IRLP node 396 for anyone looking to say hi! It's about 10:30pm Pacific time on Tuesday May 21st... I'll probably be on for another hour or two. It would be fun to hear anyone's take on my new pages. I'm not a webmaster, so I'm learning.as I go...

Do a search, there are plenty of "on the net" features on building foxhole
radios.

Someone also posted URLs here very recently.

Hello,

I have one of these nice vintage power triodes in stock. Heater is 10V
4.8A, anode dissipation is 65W and max anode voltage is 1600V. The
valve is NOS and in its original box. You will find a picture and more
data at my web site - www.demostenes.no
Just search for RS 31g.
Please contact me if you are interested.

Regards,

Arnold Goks&#65533;yr
DEMOSTENES - N6899 Balestrand, Norway
Tlf. +47 5769 1340 Fax +47 5769 1267
http://www.demostenes.no

Thousands of different valves in stock as well as
sockets,transformers,books,caps,resistors and
other components. Web site is updated every week.
You can order on-line.

Even more amazing is the ignorance folks like yourself have of that behavior.

I worked with a Phillipino who'd been a teen during the Jap invasion. He said most expected the Japs to act like the Americans or the Spanish before them. The didn't! They beat him and his dad half to death, raped his mother and sisters then hauled his older brother off to a labor camp and his sister to a brothel where both died within a few months. He survived because his mother was from a jungle tribe and they hid with them. If that's not enough, consider what happened in China and Korea. Worse yet, modern Japanese still have shrines venerating the perp's of these atrocities! That's reality!

Sounds typical of the behaviour of invading forces
when colonising. The Brits were no different, the Union
Jack flag being known as The Butcher's Apron.

And just what effect do you suppose that your own Yankie
missiles had on the civilian population of Iraq, Bosnia, etc?

Yup - that's right; your fellow humans were burnt to death,
had limbs blown off; were crushed to death under buildings.
Doesn't seem much difference between the Japanese of the
1940's and the Americans of today in terms of the effects
on their victims, does there?

In terms of the American involvement with the Japanese,
the matter of Pearl Harbour, far from being a day of infamy, was
an honourable attack. The stupid Secretary Of State was playing
childish games in respect of not giving an audience to the
Japanese ambassadors, and that is the _ONLY_ reason
that the USA had no warning. The Japanese were entirely
honourable in declaring war and then attacking.

No one can say their nation has not committed atrocities in the name
of the nation.
But lets hope we all learn from their, and our, errors. But more
importantly, lets just let bygones be bygones.

3663. Lead Acid Batteries charge

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-22 15:00:35 UTC
From: Frank Dinger <gm0csz.kn6wh@ntlworld.com>
Message-ID: <7pOG8.11349$D16.2527741@news6-win.server.ntlworld.com>
Source record: 43953

Powering my Amateur Radio station and desk lighting from 12V lead-acid batteries I am charging the batteries to 13.8 V (sealed batteries to 13.5 V) Occasionally the non-sealed (non gel-type) batteries are charged to 14.4 V for a limited period.
I would like to know when the batteries are discharged how much the charge is reduced in respect of the total charge available when the voltage drops from 13.8 V (13.5V) to 12.5V.
With the total charge available I mean the charge in Ah (Ampere*hour) from fully charged to discharged state , fully charged meaning 13.8 V , discharged meaning a terminal voltage of 11.5 V .
Although there is a lot of information available on the Web re lead-acid batteries , I haven't been able to find this info.
Perhaps someone on this NG knows a site showing a graph 'Percentage Available Charge' against 'Battery Voltage' .

TIA for any advice

Frank gm0csz.kn6wh@ntlworld.com

OK, pick it up on a crystal set and copy it. I was responding to the statement that a crystal set was best suited for CW, but could also pick up AM.

I disagee with your premise that A1A is AM.

Modulation implies adding audio to a carrier. Simply doing on/off keying adds no modulation (disregarding key clicks etc)

The only reliable source for this info is the manufacturer,
The characteristics are different for each battery although with enough data you could probably come up with an average curve chart for each type such as lead-acid.

No, no, no, dumb bear. Of course I should have calculated the power
ratio, not just the voltage ratio, and should get the values you found
from Reg's program. One could also correct the above values by adding
10 log (200/120) and 10 log (300/120) to them.

Cheers,
Tom

The best way to find this info. is by your own test. Put a known load on the
fully
charged battery and watch the voltage. when it gets to your cutoff volyage, you
calculate the total amp hours.

The main problem is this will change as the battery ages.

Please humor me with a straight answer to what seems a simple question. If I wind a simple single layer RF coil, what is the winding pitch in terms of the coil length and the number of turns? Or, conversely, if I know the pitch and number of turns, what's the length? For instance, if I wind two turns on a 3/8"x16TPI bolt, so the pitch is 1/16", how long a coil does that two turns make? How long a coil is 8 turns wound on the same bolt?

Cheers,
Tom

Hi Frank,

It depends on the type of battery you have. In wet / flooded batteries there are different make
ups of the plates. Some use lead/antimony and some use lead/calcium.

Deep cycle batteries typically are fully charged at 12.8 volts. They are 50% discharged at 12.2
volts and flat dead at 10.8 volts.
In order to measure the voltage they need to set for about 6 hours or so with no load or charge
connected. It is also a good idea to load them a little first to get rid of the surface charge that
can be on them which will give you a false reading.

If you can test the specific gravity of each cell that is a good indicator of charge also. Get a
hydrometer with a thermometer in it as temperature matters. On the site below there is a charge
curve for various charge levels for specific gravity as well as voltage. Look under FAQs.

Keep in mind that other plate makeup will show different readings.

It is best to float them when not in use at around 13.2 to 13.4 volts. They are very happy long
term at these voltages. But the float voltage also depends on the make up of the battery and it's
temperature. Find out from the manufacturer what they should float at. A .1 volt difference is
very important. Charging is normally done with voltage limited from 14.2 to 14.8 depending on
the type of battery. As a general rule the charge current should not exceed 25% of the amp hour
ratting.

You should never discharge a "deep cycle" battery to more than 50% of it's capacity. Non deep
cycle (starting types) should not be discharged anywhere near that much. In either case the
deeper you discharge them the shorter life expectancy.

Here is a site that gives some info on the Rolls batteries, considered to be kind of the Caddelac
of deep cycle batteries.

http://www.dcbattery.com/rolls_cs_plate_discharge_curve.html

http://www.dcbattery.com/faq.html

> Thank You,
> Jerry KB7BKN
> Summit, Oregon

From the manual:

1) Turn the FUNCTION switch to SWR.
2) Pull the SWR SENS switch out and turn it fully
counterclockwise.
3) Apply power to the transmitter and tune it for
maximum RF output reading. Disregard the Power
Meter reading at this time.
4) Turn the SWR SENS control clockwise for a midscale
meter reading. A minor "touch-up" tuning of the
transmitter may show an increase on the Meter. This
indicates a closer match between the transmitter and
the transmission line.
5) Turn the SWR SENS control clockwise to give a full-scale
meter reading.
6) Push the SWR SENS control knob in and read the SWR
directly on the lower meter scale.

So - what's the url for your page?

3678. Re: Minimum Loss Pad

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-22 20:36:48 UTC
From: James Horn <jimhorn@svn.net>
Message-ID: <3cebf350@news.svn.net>
Source record: 43966

OK - I spent some time with a notepad and got the following:

If Zin = input impedance and Zout = output impedance and Zout > Zin (if not, just swap 'em so it is true),

Find the impedance transform ratio, k=Zout/Zin (k>1). Find another constant: m=sqrt(k*k-k)

The pad has a resistor in parallel with the input with a value of:

Rparallel = Zin ((k+m)/(k+m-1))

It also has a resistor between the input and output with a value of:

Rseries = Zin * m

The loss of the pad in dB will be:

Loss(dB) = 10 log (k + (1+m)^2)

For example, I tried a Zin of 50 and Zout of 75 and got:
k=1.5; m=.866; Rparallel=86.6; Rseries=43.3; loss=7.2dB

Hope this helps...

Jim Horn, WB9SYN/6 (series / parallel resistances and algebra)

3679. Re: Minimum Loss Pad

Newsgroup: rec.radio.amateur.homebrew

From: James Horn <jimhorn@svn.net>
Message-ID: <3cebf3e4@news.svn.net>
Source record: 43967

Sorry I missed a detail - the calculations I showed are for unbalanced lines. For balanced lines, the series resistor is *two* resistors, each with half the value to make a symmetrical, balanced pad. In my example, Rseries is shown as 43.3 so you'd use two 21.6 ohm resistors, one on each side between the input and output (*not* a common grounded side).

Jim Horn, WB9SYN/6

From: James Horn <jimhorn@svn.net>
Message-ID: <3cebfef5@news.svn.net>
Source record: 43971

Not my day - the loss formula is wrong. It should be:

Loss (dB) = 10*log((k+m)^2/k)

or 5.72dB for the example.

Sorry folks! I have checked it against examples in my "Electronics Engineers' Handbook" and get the same results so my equation swinging seems to have finally hit the mark.

I would disagree with that statement...

Modulation implies adding *information* to a carrier. That information is
often audio, but it can be something else. Video (TV station), data
representing text (pagers), data representing God-knows-what (802.11
wireless LANs), whatever.

Text encoded in the International Morse Code is also valid information.
Information that's usually added to a carrier by turning that carrier on and
off. I don't think it's at all wrong to call that modulation, and the
parameter being modulated is certainly the amplitude.

==========

The best way to find this info. is by your own test. Put a known load on the
fully
charged battery and watch the voltage. when it gets to your cutoff volyage,
you
calculate the total amp hours.

The main problem is this will change as the battery ages.

Bill K7NOM
==========
> Only sensible reply I've seen in awhile regards lead-acid batteries -
> Hope Frank and others read it.
>
> Gord - VE1AJF
=======
Of course I did , I already am in the process of making an adjustable
(battery discharge) load based on an opamp ,some pass transistors and a
number of car headlight bulbs complete with a timer/counter such that I can
discharge any battery at a set rate (up to 10 amperes) down to a set

voltage.

Thanks to all responding to my above query for their advice .

For your info ,my station runs on 4 ea 75Ah (wet lead-acid 'leisure') battery, located on a well ventilated loft and a number of gel-type sealed batteries located in the shack . They are charged by a 150 Watts wind generator soon to be accompanied by 2 ea 64Wp Solar Panel. Wp= Watt (peak)

I think the ITU modulation definitions tend to agree with your
disagreement ;-). I looked up http://www.itu.int/ars/rr/aps01.htm,
and the definition of the first "A" is specifically:

1.2 Emission in which the main carrier is amplitude-modulated
(including cases where sub-carriers are angle-modulated)

1.2.1 Double-sideband A

Normal CW Morse telegraphy is A1A - double-sideband amplitude
modulation of the carrier, carrying quantized/digital information
without the use of a modulating subcarrier, for telegraphy. This is
made pretty clear in the table down in Part B of the page I cited
above, in which CW Morse telegraphy is specifically listed among the
"Amplitude Modulation" examples.

Sending Morse by switching an audio tone (subcarrier) on and off, and
then amplitude-modulating this onto a carrier, would be A2A.

So I guess I never really needed that BFO on the receiver, and I shudder to think how many receivers have an unnecessary CW position. We simply could have switched to AM and copied the amplitude modulated signal.... Right!

3690. Re: Coil length and winding pitch

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-23 01:36:43 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3CEC47AB.65B2FF56@eznec.com>
Source record: 43982

Pitch is the center-to-center distance between adjacent turns, so the length = pitch * number of turns. If you want to get fussy about the length, I suppose you should add one wire diameter, that is, length = pitch * number of turns + wire diameter. This makes the assumption that the coil ends just overlap. I think most (or all) writers ignore the wire diameter business, since beyond a few turns it becomes insignificant.

The two turn coil in your example would then have a length of 2/16" + the wire diameter, the 8 turn coil 1/2" + the wire diameter.

Allow me to elaborate on my poor choice of words:

When I said that a foxhole radio was better suited to CW reception, I was alluding to the fact that this type of radio has a very high distortion of AM signals, due to the nonlinearity of the detector junction, and the fact there is no filtering of the detected signal. And yes, you CAN copy CW with just a detector, no BFO, nothing. Early CW receivers had no BFO, the operator simply listened for the duration of the carrier wave (hiss).

Your receiver, even if it doesn't have a BFO, is definitely reproducing the signal as it was transmitted. Imagine that you hooked a speaker in series with the code key at the transmitter. What would you hear? It wouldn't be a nice 700Hz keyed sine wave.

If you go back far enough, you see that there is some evidence that Morse never intended his telegraph code to be decoded by ear. It was to wiggle a pen on a moving strip of paper; Morse was intended to be decoded by eye. If that intent had survived to the invention of radio, a BFO would have been unnecessary; a BFO-less receiver could have driven the pen and delivered perfectly legible code. (it may also be instructive to note that the early wireline telegraph equipment had no BFO; the operators were actually able to copy the clicks and clacks...)

Today, you could build an IF-DSP receiver in which the appearance and disappearance of the carrier would be interpreted by the CPU as Morse elements. Perfect Morse could be displayed (within the limits of QRM, QRN, and the sending operator's fist!) without a BFO ever existing.

The BFO is an enhancement added to allow a human operator to read a code that was intended to be read by machine.

Early CW receivers were clockwork mechanical coherers.
The operator listened for the sounder ratio of dits and dars

As a schoolboy a group of us tried making the foxhole radio,
with razor blade and graphite pencil detector
Could never get it to work, had all had to resort an OA47 in the end

For any crystal-type receiver, one had to have either a very close local ground wave, or a strong skywave. Or, alternately, a long enough antenna to catch what little was out there.

I'm currently researching the idea of using deep-cycle marine batteries.
A huge battery is cheaper than the stupid little 12V 7AH battery my UPS
needs.

No, I won't be using the huge one with the teensy UPS. I have a pair of
huge old Elgars I got because the charging circuit was overcharging and
ruining the 4 12V 15AH batteries inside. I'm thinking of either repairing
and beefing up the charging circuitry or removing it entirely and kludging
in a real battery charger with some beef to it.

I could get four of the marine deep-cycle batteries cheaper than *one* of
the 12V 15AH batteries.

I'm still lookin' to buy a used hf transceiver or transmitter/receiver combo.

Something like the Pixie2 by H.S.C. or the GM40, WM-20 by Small Wonder Labs, the 49er by Norcal QRP Club, or the SP-750 from Lectrokit.

With my limited finances I thought it would be a great way to experience different modes (I've only used VHF/UHF FM), and I would love to find something that can help me learn how to homebrew while giving me a working example and some radio fun!

Thanks!

I keep my ARES Packet Node on a "deep cycle" battery like Russell describes but got a wet cell intended for electric outboard motors vs a gel-cel cuz its mucho cheaper (<$50) than gel-cels of the same rating. I "float" it at 13.8V using a charger made for that purpose so, when (not if) the AC power fails the station doesn't even notice for at least 24 hours. IIRC the charger was well under $100US and has yet to over-charge the battery enough to require water.

The "house" batteries in our motorhome use the same system.

Also, just bought a smaller portable wet cell intended for lawn tractors from Walmart for $15! Figured the portability was worth that small price.

In my home town of Portishead, I didn't need a BFO
to copy Portishead Radio, although it was a challenge
to read the inverse Morse caused by the fully quieting
of the keyed carrier and normal noise in the gaps.

A friend of mine clued me in on an often overlooked source of good storage batteries. Just go to your local golf course and ask them if they have any old golf cart batteries. These are usually replaced when their capacity is only slightly diminished, and have plenty of life left to power radios, etc. The golf courses are GLAD to give them to you, as they are a disposal problem to them.

Just for the record this is not true. Today the 3 so-called 'war shrines' simply symbolize the war effort and visitors are paying respects to family or friends who were lost in the war (as you might reasonably expect to find in any other country).

For your information, my office for the last 12 years has been situated less than 100 meters from the largest "war shrine" (Yasukuni Jinja) and my car park is located within the grounds of the shrine itself (they operate a paid parking system for private vehicles to utilize spare land) so I walk through the shrine at least twice each day and have a good opportunity to gauge the atmosphere.

There is no veneration of the war in Japan and there is no basis for your comment.

Dose anybody know of a simple but powful morse code transmitter circuit one can build.

I have heard where these circuits are interesting to build and simple in construction.

Thanks Craig

I wouldnt think twice about the 7360 in comparison to a solid state mixer. The tube is hard to keep balanced, requires attention often and is hard to replace. Not too many of them left floating around out in the market. The 7360 was replaced early on in several SSB rigs of older vintage by mods adding the diode ring modulator. They work well and have far better balance. I know the purists out there would love to see more tubes used in service, but as a lifelong technician, I'd go to the diodes in a heartbeat.

And, consider that AT&T used the ring mods by the millions for years in analog voice carriers and they served well. 4 ea, 406 or 404A diodes in a ring, drive them with just about a +7 DBM of carrier and you were off and running.

Not sure what you mean by "powful," but the Ramsey
Electronics kits are great for learning. Minutes after I
finished my 40 meter transmitter, I worked a station
3,000 miles away...

Fair Radio in Ohio have the 7360 NOS for $ 15.- each. I think that is
cheap, the usual price is much higher.

: equipment). Apparently this wasn't good enough so he linked up a solar
: system to it as well. There were a couple of other attachments also.

I'm not sure what you have in mind. Do you want a solar powered battery?
or just a way to have a back up 12v supply?

Astron Power Supply makes a few of thier power supplies with a special
circuit (the -BB option) to attach a 12v battery. This turns the Astron
into a sort of 12v uniteruptable power supply. During 'normal' times the
power supply charges the battery, but if commercial power should fail the
battery takes over powering the equipment.

I have this setup running my APRS WX station. The BB option is a special
order from most retailers however (they usually don't stock them) As I
understand it, the special circuit not only charges the battery, but
protects the power supply when commercial power fails and power is drawn
from the battery. NOTE: I found out the hard way I had to reduce the
voltage on my Astron to keep from over charging my battery.

For information on solar (and all types of re-newable) energy check out
Home Power Magazine.

Re: Swan and Siltronix Radio replacement power cables.
"The current 12 pin "Cinch-Jones" power cable socket part number."

Cinch-Jones no longer makes this connector "socket." I do a lot of Swan and Siltronix radio work, so I've done the home work for you. Molex sells the same type connector.

Just for your mental notes...

The Siltronix and Swan power connector 12 pin socket is available from Newark as part number 14F2451

This is a current Molex 3300 Series Socket with Cable Clamp S-3312-CCT

OK you Swan and Siltronix guys... have at. If you haven't been by the Swan Siltronix web page yet, you can find it on the

http://sonic.ucdavis.edu Amateur Radio Page, about half way down.

3713. JFET Audio Mute Switch

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-24 02:15:13 UTC
From: w.harbourjr@worldnet.att.net
Message-ID: <deafe3d9.0205231815.4cbb331c@posting.google.com>
Source record: 44005

I've got an MPF102 mute switch in between my NE5532 preamp and a LM386 in the audio chain of a simple superhet xcvr. I'm using the T/R switch from the SW30+ qrp rig. The final PA in the transmitter chain is a 74HC240 which is putting out about 1/2 watt. On transmit the audio signal is blowing by the FET (the FET will not mute...or only slightly) and is ear splitting loud. I tried another FET there but it did even worse. Obviously the NE5532 is putting out more than the FET can block. Is there another FET I could use there and still hear some side tone leak through??

Your help is greatly appreciated!

17AH gel cells will barely run an HT. High current drains are
impractical because gassing within the cells insulates the plates
faster than the gel can absorb and causes the internal resistance to
rise out of hand. Current drains should be limited to 20% of AH
rating (and with boat batteries too).

Big as you can get (into your tray) Marine/Starting batteries are a
pretty good compromise if you have to use it in your car.

Your preamp is probably swinging rail-to-rail in response to the transmitted signal. One thing I've done is to put a couple of back-to-back diodes across the preamp stage feedback resistor. This limits its swing to a level the FET can handle. Unless you somehow limit the output swing of the preamp, you'll have a lot of trouble finding a FET to handle it.

I used this scheme in the "Optimized QRP Transceiver" described in August 1980 QST.

Hey, Richard,

What voltage setting did you end up using? I spent $toomany on a
"smart" charger but I have a couple older PS's about that I'd like to
use like you do the Astron.

I was told that these shrines commemorated the officers who ordered and
the men who perp'd these atrocities; this by an American also living in
Japan. If that is untrue then I was misinformed. Sorry.

OK! Time to discuss the USA atrocities during their
invasion of Vietnam, rapes, massacres, etc.

Also, any war shrine or memorial is a hideous thing.
Anyone who goes around the world fully prepared
to wound and kill his fellow man has only himself
to blame if the tables are turned on him.
To commemorate such deaths is to glorify
the organised murder that is war.

It was so long ago I forget. I contacted the manufacturer of my "deep
cycle / marine" battery and asked them for the long term float voltage and
set it to that.

I *still* have to monitor the liquid level, but it does not disapear
anywhere near as fast now.

You could also mute the LM386 by connecting the bypass pin (# 7) to either Vcc or ground via a transistor switch, or a diode from a supply that switches between rx/tx.

The Optimist QRP 80 SSB tranceiver from SM6LKM uses that (to Vcc), see http://home.swipnet.se/~w-41522/qrproot.html

This would work fine, unless of course you want to use the LM386 for a sidetone output during transmit.

Industry standard float voltage is 2.3 volts per cell.
That's 13.8 volts for a twelve-volt lead-acid battery.
We use 54.something volts for a 48 volt string in telecom.

Atrocities.... You mean like those committed during the Japanese
invasion of Manchuria in the early 1930's ? Rapes. Torture.
Massacres..... That sort of thing.

Is that why you changed the subject again. You start spouting your
strange version of WW2 history and then immediately change to an
entirely different conflict....

Hi Folks,

For those of you looking to build a K2 or whatever for a high performance rx take a look at the following just being described in the UK's Radcom:

http://www.warc.org.uk/cdg2000%20files/release1/CDG2000.htm

i.e.

"We do not claim that this is the last word in analogue circuitry. That, most definitely, it is not; in spite of those who say that analogue circuitry is dead. It is however designed to offer the best performance we could achieve with a design that is reproducible, and on a practical note, its modularity lends itself to replacement of modules with others as time progresses. Unlike many commercial transceivers, it does not offer unlimited bells and whistles, many of which, on inspection, appear to be no more than sales gimmicks, but we have included those features that we consider to enhance operation. What it does do is to beat the pants off most of them in regard to performance. Receive IP3 (third order intercept) is about +40dBm. Noise figure is around 10dB. On SSB, 10dB(S+N)/N is about 0.22uV (-120dBm). Its oscillator phase noise levels and close in performance achieve -140 dBc/Hz at 9KHz offset from carrier and -150 dBc/Hz at just over 20 kHz on the 20 metre band"

"On SSB this gives a noise floor of (-174+10*log(2200)+10)dBm, or −130dBm [3]. With an IP3 of +40dBm and a noise floor of −130 dBm, this gives an IP3 dynamic range of 113dB using the formula: IP3 DR = 2/3*(IP3-MDS)."

I guess most of the solid state kits are probably more practical than
tubes these days. But you can get a fair amount of power out of just a
simple tube setup. The problem is it's sort of hard to find tube parts
these days. Used to, any junk tv had most of the parts to build a
simple transmitter. "transformer, etc".
Just a simple 6v6 circuit as the one in the old 1949 arrl handbook can
put out a good bit of power compared to a QRP solid state kit. I built
two versions of that when I was a novice. With a single 6146 and a
capable power supply you can do an easy 50 watts output. This is the
main circuit behind an old heath DX-60 as an example. But these
days it's probably more practical to build a solid state amp to go
behind the solid state QRP transmitter. Either that or rebuild an old
boatanchor CW rig. There are loads on e-bay I bet. IE: heath
dx-20,40,60's. Viking rangers, etc, etc. MK

The problem with DX-20s, etc is their 'collector value' nowadays. They
used to be nice for a starter rig but nowadays that has gotten
impractical.
Somewhere on the web there's a set of good instructions to recreate the
Ameco AC-1...which these days might snatch $100+ on tha'bay.
As for a solid-state QRP rig, yes thats much easier but any significant
power requires a bit of savvy to overcome the homebrew oddities that
creep up in the amp stages, often at the immediate cost of a new
(expensive) power transistor. The plus side is that if you've never
worked QRP before you'll be thrilled at the contacts you can make with
one watt or so and thats a very rewarding experience.
All that being said, homebrewing a simple tube rig is probably the
better option if you have access to some junkbox parts. I'd stay away
from the old-timey one-tube jobs unless you just like the sound of a
chirpy signal...ie forget about the one-tube 813 MOPA designs.

Recommendations vary among battery manufacturers and even for models made by the same manufacturer. Get their specifications and follow them.

Remember that float voltage is temperature dependent, and the specified voltage usually is at 25 degrees C. For other temperatures, compensate according to the manufacturer's spec (-3mV to -5mV per cell, per degree C). If you see a lot of temperture variation, consider getting a temperature-corrected charger. Your batteries will last longer!

I've found that, for reasons that I don't understand, amateurs call all sealed lead-acid batteries "gel cells". All the sealed lead-acid batteries I've seen, with the exception of cylindrical Gates cells, have liquid electrolyte. Sealed lead-acid batteries with gelled electrolyte do exist, but they're relatively rare. So without other information, I'd assume that the Mendelsons "gel cells" have liquid electrolyte, not gelled.

Hello All,
I have a really nice 110w high-split low-band Motorola Mitrek that I would love to convert to six-meters. If anyone could point me in the right direction of how to retune the unit and for a source of 52.525 channel elements, I would greatly appreciate it. thanks!

Ian, KF4AON
(please reply via email if possible...thanx!)

3744. external rx provision on hf transceivers

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-25 05:44:41 UTC
From: Anthony Roskilly <Morse.Key@btinternet.com>
Message-ID: <acn8c9$op4$1@knossos.btinternet.com>
Source record: 44036

Hi,

was wondering if anyone had moded a transceiver
to allow use of an external rx, ie spur off the antenna
from the rx side of the transceiver. I presently own
an FT902 and FT102 and both these rigs have the
facility to use an external rx. Very few more modern
rigs provide this facility.

I note that the TS870 does
have ext rx socket, but reading the newsgroups I see
that the signal level on the main rig drops when using
the ext rx... does this mean that Kenwood just T off
the rx antenna input? - I would have thought some sort
of matching would be required to minimise signal loss.

I would like to move over to a more modern rig with
QSK and would like to hang on to the FT102 as a
2nd RX and back-up rig, so any info on providing a
ext rx o/p for say an IC735 would be gratefully received.

73 Tony G 3 Z R J see you on CW.

My favorite place to get channel elements is Channel Element
Headquarters
in Cincinnati, Ohio. 800-237-9654 They are a clearing house for
trading used channel elements. They test and warrenty every element
they ship.
The other choice is to send elements to a crystal manufacture and have
them re-cystalled. Someone like International Crystal Manufacturing
800-725-1426. This take longer and is more expensive.

With the disclaimer that I have only returned 2 meter and 440 Mitreks,
when I looked into it, it appeared you could simply follow the
Motorola
tuning procedure to re-tune it.

Don't even bother!!
I WAS at Dayton, and those "new" batteries had not been charged for 4 YEARS(at least that was what I was told by a Mendelson employee).
So new, means NOS, but with SLA batteries, if you don't charge them once in a while, they lose much of their capacity.

Here is a useful relationship applicable to single-layer inductors:

n = 2.53(L/Sw)^1/3, where n = no of turns, L = inductance in uH &
Sw = winding pitch as described by Roy below.

If you have the chance see ARRL QEX Sep/Oct 2001 followed by Letters
to Editor, p61 in QEX, Jan/Feb 2001.

One tube MOPA?

A Master Oscillator plus Power Amplifier transmitter would be at
least 2 tubes, unless you're using a dual section tube, which the
813 is not. A one tube transmitter would simply be a keyed power
oscillator.

Even MOPA designs often have some pulling (chirp). A better
minimalist design uses 3 stages, oscillator, buffer/driver, and
power amplifier. The buffer/driver isolates the oscillator from
the keyed amplifier stage, reducing pulling problems to near nil
(except for power supply sag, but that's a different issue).

Let's see...that re-arranges to

L = Sw*(n/2.53)^3

The inductance depends only on winding pitch and number of turns, and
not on the diameter? Hmmmm. Any chance you transcribed that wrong?

Cheers,
Tom

(I have been hoping that others would check in with answers to my
original posting, by the way.)

Yep, you can find them, but I didn't know if he want to or had close
access to any hamfests. I guess most do at some point in the year.
Most flea markets and hamfests will usually have loads of junk parts
laying around for cheap. Many times people will drag the stuff out to
sell, and end up giving it away just so they don't have to haul it
back home. MK

If your read again the posting to which you replied, you will see
another reason for 'pulling' other than the number of valves in the
transmitter lineup. You power supply could have been poorly regulated.

Do you still pull?

It was a Geloso VFO into a single valve PA (a single 807, I think).
Yes, it did tend to be chirpy! A buffer stage between the Geloso unit
and the PA would have helped.

Finally had some time and here's what I found out playing with the thing.
It reads LCR with the Hi and Lo jacks, nothing with the G. With a few LCR
items that are in resonable tolerance it read them within reason. An
electolytic at 4.7 mike read 4.65 mikes, a .1 reads .12 and a .01 read .01.
Resistors are about 10%. Inductors are also close, 820 micro henries reads
800 and 3 in series reads 2.4 so it's on. On my scope I was able to see a
100 Hz sine wave in the L mode but couldn't lock on to the waveform in the C
mode. Still hoping someone has a manual who can guide me.

"Gel Cell" is a trademark of Johnson Controls (and various successors
who aquired them). It refers to their construction, where the
electrolyte is modified to a viscous goo so that it wouls stay between
the plates. Other makers may have built this type under license or
sold them under their own brand name.

Most other Valve-Regulated Lead Acid (VRLA) use a fiberglass mat to
hold the liquid in place between the plates. The term "Absorbed Glass
Mat" (AGM) refers to this type, and it too might be a trademark.

The term "sealed battery" really doesn't apply to any of these. All
have a pressure-relief valve that opens to let out the gas when the
pressure gets too high, which happens if you charge at too high a
voltage or current. The valve is supposed to reclose to keep the
liquid inside. They're also called "non-spillable", which means
they're legal for transport on civilian aircraft (for electric powered
wheelchairs, etc.) and avoid some hazardous-material limitations for
ground transportation.

Another problem is poor shielding between the oscillator and the PA.
Think of it as a capacitor switched in between the high-level stages
and the oscillator tuned circuits. Build your oscillator in a fully
shielded box, and filter every lead leaving that box (except the RF,
which should be shielded--i.e., coax). If can take a look at a
well-built older rig, such as a Johnson Ranger, this is just the
construction you will see. Or, build the oscillator in a completely
separate outboard box, with its own power supply, etc. (as in the
Heathkit external VFO).

You really have to know what you have before you can know
how to maintain them, or if they are compatible with your usage.

REAL gel cells are plentiful and available in a variety of AH
ratings. And most do not leak at all, even if turned upside
down.

Maintenance Free car batteries often use a calcium
additive that reduces the electrolyte loss and allows a greater
margin for overcharge. This doesn't hurt the ability to supply
adequate starting power, but makes for poor deep-cycle
performance, and recovery after a deep cycle. They also tend
to leak at the post, making them no better than a REAL deep-
cycle Marine or Golf cart battery that allows you to add water
as needed. BTW I have seen Golf cart batteries on sale at
CostCo for a great price.

All I was stating, was that if you were for some reason forced
to use a car battery, you would be better off with a Marine/starting
or RV battery, than with a stock type car battery.

However, I don't see why anyone would want to use a stock type
car battery unless they had a bunch of junk cars in the yard, and
a low current drain accessory to run, like an old CB or 8-track
stereo, because stock type low-maintenance or maintenance-free
car batteries don't keep well in this kind of operation.

Source record: 43924

Hi Henry,
It sounds as if you've got things hooked up the right way.
Many LCR meters have what you call a 4-wire guarded probe; it sounds like your unit has a variation of this scheme, except that only two wires are used. Ott's book on low noise techniques describes the grounding scheme; at low frequencies, it is desired to have only one end of the ground shield connected. This avoids ground loops. The reason that you have two "hot" wires, is because your input cable is probably feeding an op-amp, in differential mode. Most likely, this op-amp is an instrumentation amplifier. A 4-wire probe setup would use the 3 op-amp instrumentation amplifier configuration, with two op-amps in the front end summing to a third op-amp. This acheives a very high input impedance.
I hope this answers your questionn!

That doesn't match my experience.

I've powered an 100-watt HF transceiver, a 25-watt VHF transceiver, and
an AM/FM receiver (for easy listening), plus occasionally even the lights
(when the mains are off) in my shack for over 25 years using stock lead-
acid batteries from my local discount store. They last about as long
(3-5 years) in my "shack" as they do in my automobiles.

Even the old rangers and valiants had a distinctive sound due to their
differential shift?? keying. I think thats what they called it
anyway..Been awhile since I messed with those. They were good rigs for
their times though.
I used a friends ranger a lot when I first started out, and bought a
valiant later on as a "big" novice transmitter. My first homebrew
transmitters with the single 6v6's had a slight pull, but not too bad.
You could reduce it quite a bit dependng on the tuning. So I always
listened to my own signal when tuning.

I always discuss British atrocities in NI.
Also those in the Malvinas squabble, where
evidence of Brit war crimes was not brought to
trial, not because of any lack of evidence, but
because of a pompous outcry; pomposity and indignance
that Brits could be anything like Nazis, even thought they are.
Still, after 50 years of parasitism, jumping to the
front of the queue in taxpayer-funded hospitals and
yet paying no tax, we now know that heads-of-state
are not immune to prosecution, Clinton, Milosevic; and
so it can be only a matter of time before Lilibet Windsor
is brought before the International Court for all the
atrocities for which she has been responsible.

Brit and the USA are an equally evil and hypocritical
alliance when it comes to murdering their fellow man
on the most trivial and preposterous of reasons.

The motors in these rotors require 120 VAC as does the power transformer for the meter indicator located in the control box. Your best bet is to use a 12 VDC to 120 VAC inverter to power the rotor.

Hi,

Maybe because they are very cheap? Here a new 12V 45 AH 'car' battery costs about 24 euros (~22 US$). A 12 V 7AH gel 'alarm' battery costs approx the same. A 12V 35AH gel type is >120 euros (>110 US$). Surely the gel type will be much more adapted to deep cycle conditions, but the price difference more than compensates for it. Of course, car batteries are much heavier, bulky and inconvenient to work with, but, if you have the place to put them, I think they are better.

I do not know the prices of marine / golf / etc batteries, but given the equation "price = K / popularity" (where K tends to large numbers) I think they must also be quite expensive.

Look for a sine-wave output inverter. The rotator uses a split-phase
motor with a phase shifting capacitor. These don't work very well with
square-wave AC from cheaper inverters, because the phase shifting
capacitor exaggerates the harmonics of the non-sine wave voltage.

True.

> batteries I've seen, with the exception of cylindrical Gates cells, have
> liquid electrolyte. Sealed lead-acid batteries with gelled electrolyte
> do exist, but they're relatively rare. So without other information, I'd

Not at all rare.

The typical "maintenance free" lead acid is not sealed and will
spill in some positions, and they do vent under hard charging.

The true sealed lead-acid can be operated in any position (will not
leak) and does not vent unless severely abused (venting is a last
chance method to avoid a case rupture, similar to nicd/nimh).

I have only seen two technology types of sealed lead-acids. The
gelled electrolyte type is by far the most common. The other is the
starved electrolyte, typified by the Absorbed Glass Mat (AGM)
batteries like the Optima yellow or red top or the exide "6 pack".

The gelled cells are a fraction of the price of AGM cells. They are
found in alarm equipment, "portable jump start" power packs,
children's rechargable riding toys, emergency lighting, rechargable
lawn and garden equipment, consumer computer UPS systems, etc. In
other words, nearly everyplace which needs higher capacity than a
small nicd pack, and where the weight of lead-acid is tolerable.

The typical yeasu 12v/7ah/$20 "brick" is a gelled electrolyte, and
probably the single most common sealed lead acid battery in the US.

> assume that the Mendelsons "gel cells" have liquid electrolyte, not
> gelled.

I wouldn't. But $16 is a very good price for new 12v/17ah gelled...

Ah. That explains the low price. :(

> So new, means NOS, but with SLA batteries, if you don't charge them once in a while,
> they lose much of their capacity.

If sitting for four years, I'd expect them to be almost but not
quite useless because of extreme sulfation. A couple more years of
sitting and that would be the end of them. A year or two ago I
purchased a UPS "new in box" which had been sitting since 1994. It
contained four, 6v/4ah gell cells. Of those four batts, three of
them would not charge above a fraction of a volt. the fourth
charges to about 2.1v, with nearly 0Ah capacity.

I sure hope the Mendelson batts are better...

Of course you may be able to recover the sulfated batts, but I'm
skeptical. http://www.shaka.com/~kalepa/desulf.htm

=========
1) As Roy Llewallen commented in an earlier posting ,a Sealed Lead Acid (SLA) battery is not necessarily a Gel- type.

2) An SLA 12v-18Ah costs approx US$ 25.- (in the USA)
In the UK ,Mainline Surplus -Leicester sell SLA 12V- 18Ah ,make Kiel (New Old Stock) for GBP 12.50 incl VAT= Value Added Tax) equiv to approx US $ 19.-
I have quite a number of these in the shack and am quite happy with them.

For golfers in the UK : This battery is very suitable for an electric golf trolly. I recently replaced a Yuasa model: NPC15-12 , 12V-15Ah SLA which had been rather active for the past 3 years ,by the above make Kiel battery having identical dimensions . The old Yuasu battery has been retired to the shack where it still performs well be it on loads somewhat lower than a golf trolly motor .

3) The 'cheap' car batteries referred to in the above posting might not be the sealed type .In that case it would not be advisable to have them located in the shack , for safety reasons ....because of hydrogen/oxygen venting. Venting batteries with removable caps for water top-up must be located in a well ventilated area !!

3805. Two into Motorcycle Headset

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-27 23:32:30 UTC
From: diemuse@hiwaay.net
Message-ID: <d032b7b8.0205271532.1442a0ac@posting.google.com>
Source record: 43945

Ok here's my question.

I would like to run my handheld radio and radar detector into the same helmet headset at the same time. Both devices work fine with the headset by themselves, but I would like to be able to use them both at once. Will the signal coming out the radar detector hurt the radio or vise versa.

I plan to just spice into the headset, no special devices.

Regards,

John

3806. Re: Coil length and winding pitch

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-27 23:44:56 UTC
From: Phil Rice <someone@somewhere.oz>
Message-ID: <280520020944563162%someone@somewhere.oz>
Source record: 43946

Just thought I'd buy into this one, without having read too many of the preceding posts.

"Wheeler's" inductance formula gives the inductance in microhenries to an accuracy of (if my failing memory serves me correctly) better than +/- 2% providing the length "l" is greater than the radius "R".

See any ancient copy of the "Radiotron Designers Handbook".

```
R*R * N*N
L= ----------- uH
9R + 10l
```

"R" is the radius in inches, "l" the length in inches
and if you don't know what "N" is, you shouldn't be winding coils!

There are better formulae, but this one is close enough for Government Work, and it's easy to remember.

Happy tinkering,
73 de Phil VK3BHR

3807. Old Q dope

Looking for a basic surge arrester circuit.

I have a unit with three MOV's in place, but there are no caps or neon bulb
I vaguely recall that two caps are used, one
between each prong contact and the ground, and the neon goes between the
prongs contacts. Is this correct?

I have the 120VAC caps.

Comments, or a schematic or a reference to one, would be appreciated.

I think most any volatile solvent will work. I use acetone. You can make your own Q dope by dissolving styrofoam peanuts or chunks in solvent. Do a Google search for info on this, there was a thread a couple years ago involving Barry Ornitz who IIRC is a chemical engineer. He told the whole story on Q dope.

As usual, I've got a lot to learn. What I've seen overwhelmingly at flea markets, electronics stores, and places like EH Yost are Panasonic SLA batteries. These are of the absorbed electrolyte type, in which the liquid electrolyte is absorbed into the plates and separators. http://www.panasonic.com/industrial/battery/oem/images/pdf/slaover.pdf discribes these units. In second place for the number of batteries I've seen for sale are the small Yuasa SLA batteries. I couldn't find a description of the electrolyte system in a quick search of the web, but an old data sheet I have describes the system as "suspended electrolyte". I've assumed that these are also AGM type, but perhaps I'm wrong.

I couldn't find any reference to Yaesu batteries. Perhaps you mean Yuasa. But I couldn't find a 17 Ah battery among their offerings. Do you have the part number of this apparently very common battery? I'd like to look at a data sheet to learn more about it.

Source record: 43856

NOW AVAILABLE "DIPCAGE1.exe"

RESONANT LENGTH, END-EFFECT, BANDWIDTH, INPUT RESISTANCE OF 1/2-WAVE DIPOLE.

This is a little more accurate version of WIRECAGE.exe which it replaces. It may be found easier to understand and use. It computes the resonant length, end-effect, bandwidth versus various SWR points, receiving 3dB bandwidth, center feedpoint input resistance at resonance, etc. Input resistance values are somewhat smaller than usually stated but this is not of great consequence since in practice there are a number of sources of uncertainty affecting this non-critical parameter.

The dipole conductor may be any wire gauge, rod or tube, or a cylindrical cage of any number of wires. The usual facilities are available to vary antenna dimensions and number of wires in small increments while observing computed output values.

This program is more of educational than practical value since it will be seen that at HF the trouble and expense of increasing antenna diameter is not justified by the trivial improvement in bandwidth which might be obtained.

DIPCAGE1 is contained in one 36.5 KiloBytes file. Download from website below in a few seconds. No unzipping inconvenience. Run immediately. Or it can be run without downloading.

Hi,

I have an NC 300 that was a basket case but followed me home anyway.Now
that I have the electronics working with the exception of a bad 160 meter
coil I am ready for the cosmetics.
The cabinet required a total stripping and I am looking for a side and
back view so I can see the two tone paint scheme used.So far all I have
found is front views.
Any help would be appreciated.
THANKS,
...Charlie...KC0EH...

The 3336a/b/c mates perfectly with the HP 3586 a/b/c via the HP-IB. Seems from the manual that all you have to do is connect an interface-bus cable between them, switch one to slave, one to master (via REM switch on the back) and voila, a frequency tracking exciter. (well, there are a lot more options, but I'm not replicating the manual here.)

>by themselves, but I would like to be able to use them both at once.
>Will the signal coming out the radar detector hurt the radio or vise versa.
>I plan to just spice into the headset, no special devices.

Several years ago I built a simple adapter for connecting up to THREE
audio inputs to one stereo headphone, stuffed it into a 35-mm film
canister, and put it in my "grab-n-go" kit for use in the EOC and under
other emergency situations where I need to listen to more than one audio
signal at a time. Basically, one audio input goes to my left ear, one
to the right, and the third to BOTH ears (which makes its sound appear
to be in the MIDDLE of my head). Here is my adapter's schematic:

```
Tip------------R1----------o---------+
Radio on Left | | All R1's = 6.8 ohm
Sleve----------R1----+ | | Both R2's = 33 ohm
| R2 |
| | +---\/ | Stereo (Right ear)
Tip-----------------(-----o +------\/ | phone (Left ear)
Radio in Middle | | | +------+ jack (8-ohm headset)
Sleve----------R1----o-----(----(----+
| | | - and | are wires (except at
| R2 | the stereo phone jack)
| | | ( is wire crossover
Tip------------R1----(-----o----+ o is wire connection
Radio on Right | + is wire bend
Sleve----------R1----+
```

Basically, the radios on the left/right feed the earphones on the
left/right (assuming you have the headset on correctly!-) and the radio
in the center feeds BOTH earphones. There is nothing magic in the
particular resistor values shown, since each radio's volume control
can be used to adjust relative volumes; the above values were simply my
engineering guestimates, and they've worked well. I've seen fancier
versions (using more resistors, op amps, and/or transformers), but I've
seen no reason to change.

>the ground, and the neon goes between the prongs contacts. Is this correct?
>Comments, or a schematic or a reference to one, would be appreciated.

A neon bulb isn't going to give much surge surpression (yes, it should conduct when a surge appears, but it'll only carry a milliampere or three, so it won't dampen much of the energy in a true surge!) However, MOV's (Metal-Oxide Varistors) of many voltage and energy ratings are available.

The most common circuit I've seen uses three MOV's, one from each of the three prongs to the other two.

If you would also like some line-noise filtering, the common CORCOM line filter looks like this (the schematic is on some of them):

```
---+-----L----+---
| | For their 250V 3A KRF model
C1 C2 ---------------------------
Line | | Load L = 1.0 millihenry
In ---(----------+--- Out C1 = 9000 picofarad
| | C2 = 2800 picofarad each
| C2
| |
---+-----L----+---
```

Source record: 43864

Hi, All!

I need an advise from professional amateurs and radiosportsmen.
What is better, when building phase noiseless DDS frequency synthesizer:
high frequency resolution or quick responce ?
By responce, I mean time between frequency selection command and
frequency value appearance on output of synthesizer.

For ex:

- 1000 Hz resolution and 1000 millisec responce
- 100 Hz and 10 sec
- 10 Hz and 100 sec
- 1 Hz and 1000 sec
e.t.c.

Thank you.

I've been using them for nearly 15 years here and no problems. Car batteries hold up fine as long as you don't overcharge them, don't let them discharge too far, and keep the water up in them. But I do prefer a marine deep cycle if I had my choice as their design suits radio use better. But a car battery will work just fine. I'm running a 706 on one right now. I use a fully automatic charger to keep the charge up, but a trickle charge will work fine as long as you remember to unhook it when you have a full charge. Heavily discharging a car battery will greatly shorten it's life and capacity. All long as you avoid that, you won't have much trouble. A deep cycle can handle heavy discharges better, but even with those it's best not to heavily discharge them. I never heavily discharge any of those lead acid batteries on purpose. Sometimes it'll happen though out portable etc. If I buy a new battery just for radio use, I get the big marine deep cycles. MK

Q dope is polystyrene, which has very low loss at RF. Plexiglas is, I
believe, polycarbonate, which is considerably lossier. You'll have
something that might look like Q dope, but it's likely to lower the Q of
any high-Q inductor it's painted on.

Charlie,

The NC-300 Cabinet is painted light machine gray on the top and top sides just like the front panel the bottom and bottom sides are a much darker color that I have never matched. The dividing line between the two colors is the chrome strip that divides the cabinet top and bottom. I have found that Rustoleum light machine gray matches the top and panel perfrectly.

Tony

Source record: 43873

A surge protector is one component of a surge protection 'system'. But the most critical component in that 'system' - the most critical component in your schematic - is central earth ground. A surge protector located far from earth ground is all but disconnected from the rest of the 'system'. Surge protectors don't stop or absorb surges. That is urban myth. A surge protector only connects a surge to earth ground. It is only one 'system' component. No earth ground means no effective surge protection.

Effective surge protectors shunt (short, connect) each wire to earth ground during the surge. Therefore wire length to earth ground is also an electronic component in your 'system' schematic. A surge protector is only as effective as its earth ground.

Seems simple......I want to connect the audio output of my rig/scanner (which is meant for 8 ohms) to the Line-In port on my computer sound card (600 ohms). I searched for a few hours, but could find no off-the-shelf circuit. I think a 8:600 ohm audio transformer is required at least, but I am concerned about limiting the peak-to-peak input to the sound card. Any thoughts?

Thanks!

Don't bother with a transformer. Just load the scanner with a 100-ohm
resistor (some AF amplifiers need a load resistance to develop their
full output voltage) and hook it up directly.

Thanks to all.
I phoned G3VA Pat today, since he mentioned (TT Radcom June 2002) a product detector using ECH35 (6K8) which has been used in an Eddystone receiver since WW2. I said it is probably no product detector since the input levels are not proper for ssb, but it is interesting although Telefunken made a similar circuit in 1936 using ACH1Gr. So I will provide some text and circuit diagrams to Pat. Hope it is allright to quote some of the information given, particularly by VE2BVW and G3RZP?

Skip, previous message, please.
Ok, found solution with responce time better than microsecond.

I have an idea to build DDS with own phase noise better than -200..300 Dbc.
Some mathematician who can deal with irrational calculations can make it
better up to -360 Dbc. I'm looking for testing tools. Where can I
find software tools, which can measure phase noise ?

Thank you.

So, a surge protector would be of no use at a tower mounted
repeater, or on an automotive or aircraft radio, eh?

What? Surge suppressors are used in those situations?
And they work?

Hmmm, something must be wrong with your theory.

Earth has no mystical surge absorbing properties. It is just
a big old sheet resistance with varying potentials between
its various points. It's a handy thing if you *want* to produce
ground loops, or inject noise into sensitive equipment, or if
you need a lossy counterpoise for an unbalanced antenna,
but otherwise isn't of much interest to someone trying to
protect equipment from spikes and surges.

Equipment needs protection from transient voltages
across the equipment power leads which can drive
harmful currents *through* the equipment. The way a
surge suppressor does this is by providing a very low
impedance in *shunt* across the equipment. This very
low impedance makes it impossible for a high transient
voltage to appear across the equipment.

Varistors (MOVs) do this because they have a peculiar
property of being very high impedance below a certain
potential, and a very low impedance when that threshold
is exceeded. Provided that the surge doesn't exceed
their joule rating, they rapidly recover to a high impedance
state when the surge has passed, allowing the equipment
to return to normal operation.

(Gas discharge tubes, and zeners, can also perform this
function, though zeners generally don't have a large joule
capacity, and gas discharge tubes won't quench on a

DC line until equipment power is interrupted.)

To maximize a shunt suppressor's effectiveness, it may
be helpful to add a series impedance to the protected lines,
after the shunt element. In DC lines this normally takes
the form of relatively high value series chokes. In AC lines,
the chokes have to be smaller value, otherwise they start
to have a significant effect at the *operating* voltage's
frequency. Fortunately, spikes have a rapid rise time,
equivalent to a high frequency, so a relatively small
value choke will have sufficient impedance to be effective.

No mention of Earth is needed for any of this. It is just
something *over there* that we don't much care about
unless we trip and fall face down on it.

In fact, *avoiding* contact with Earth is generally advisable,
unless such a contact can't be avoided due to a need to
use it as a counterpoise for an unbalanced antenna, or
because the electrical code requires a safety connection
to Earth in a particular mains powered fixed station installation.

Earth is just filled with noise currents, and that can have
an adverse effect on the SNR achievable with sensitive
equipment like a radio receiver if Earth becomes part of
the power or signal path of the receiver.

Gary

Unless you need the DC isolation provided by a transformer (and in
certain situations you might in order to break a ground loop), there is
a simpler way to deal with this problem. Just terminate the rig audio
with an 8 ohm resistor and *bridge* the sound card input across the
resistor. It is standard engineering practice to use a bridging impedance
that's at least 10 times the terminating resistance as a way of coupling
between a low impedance output and a high impedance input. You
aren't quite at 10x, but it is close enough that it'll work.

A pair of back to back diodes will clip the audio at 0.6 volt if you need
to limit the audio level into the sound card. You should try to keep the
audio level from the rig below this clipping point to avoid distortion, but
if it does accidently stray too high, this sort of clipper will protect the
circuits in the sound card from the overload.

Depending on the bandwidth you are after:
(a) a complete IF filter from a radio with a 10.7 IF; or
(b) individual xtals from such a filter.

Note that the individual xtals will have their centre frequencies
distributed around 10.7 to achieve the requred bandpass in some form
of ladder configuration, so you will need to try each one for the
exact freq you want.

You really don't need to worry about "impedance matching", unless your rig/scanner output is exceptionally quirky. It perhaps wouldn't like a load much lower than 8 ohms, but higher is almost certainly just fine. And the line-in of your computer sound card is likely rather higher than 600 ohms, actually, and in any event won't be bothered by a lower source impedance. The thing you DO need to worry about at least a little is _level_ matching: the rig's output level should be adjusted to something in the range the sound card can handle gracefully. You MAY ALSO wish to have ground loop isolation, and a transformer is one way to get that. But you may well NOT want an 8:600 transformer, because that will step up the voltage to a level that may be greater than the sound card is happy with, unless you turn down the rig's output so far that noise will begin to dominate.

Cheers,
Tom

For future reference, if you can find a clean spot on your scabby cabinet and bring it to an auto paint shop *before* stripping it, they can do a computer color match and mix you whatever sort of paint you need to repaint in the original color. Go to an auto paint supplier, the guys who make paints for the local body shops. They can make up quarts, spray cans, whatever you need. Then you can strip, prime, and repaint. Or just clean, naval-jelly, clean, buff, clean, (did I mention clean?), and repaint if your original paint isn't too awful.

Is there a reason why it has to be right on 10.7MHz? Because most
people making filters using available crystals seem to look at
what's available in quantity and cheap, and pick the most suitable.
So a completely different frequency might be a better choice.

But I'm assuming you want 10.7MHz because you have filters there
for a wider bandwidth, and these crystals are for a narrow filter.
And I can't see any common use for 10.7MHz crystals.

Can you get by with choosing a frequency where you can get cheap
crystals, and then make two separate filters, one for wide and
one for narrow, or if wide is sufficiently wide, IF transformers?

If you need two bandwidths, and can't choose some other frequency,
maybe you'd want to consider using two separate IF strips. Convert
the incoming signal to an intermediate frequency, and convert that
IF into two separate frequencies via two mixers and oscillators.
Then duplicate the IF circuitry, but with different filters. Active
components tend to be cheaper than special crystals.

Or do a dual conversion, with the first wide IF using a frequency
where you can get a good wide filter, and then convert to another
frequency where you can get cheap crystals. Bypass the home-made filter
when you need the wide-bandwidth.

Sometimes solutions require making a more roundabout trip to
the answer.

If you can get by with crystals in the 10.7MHz vicinity, 10.240Mhz
crystals are a commodity part, what with a binary division bringing
it down to 1KHz, and they are used as conversion oscillators from
10.7MHz to 455KHz (yes, they are 5KHz off for that, but the crystals
are cheaper because they are available, and so receivers using
such crystals use a relatively wide first IF filter).

I was going to say you could get 10.7MHz ceramic resonators, but come to think of it, I'm picturing oscillators (intended for testing 10.7Mhz IF's) which use a 10.7MHz ceramic filter as the frequency determining element.

don't understand why the transformer shouldn't be important, a friend
just damaged a port on his computer and it could have been avoided
with transformer. He got some old data modems and would desolder two
transformers to avoid further damages

Impedance is not important. But I would use a series resistor as well
as the 100 ohm resistor across the audio output to avoid overloading
or saturating the transformer if it is small.

Try www.sescom.com

They have boxes with pre-punched panels (no double DB9's though) and
also sell the DB9 punches (expensive!). Check out the 'plastic
box-it' - copper clad plastic boxes. Haven't tried these myself but
probably a lot easier to fashion a DB9 hole in plastic than aluminum.
They also offer custom order punched panels - the setup fee is high
but not unreasonable in bulk.

==========
8:600 Ohms means a transformer winding ratio : sqrt 8 : sqrt 600 = approx
0.12 or 1 : 8.6
So any transformer with that order of magnitude winding ratio will do the
trick. Depending on which audio freqs are to be transferred , a small power
transformer 120V--> 12V will probably be OK.
Or small audio transformers from BC radios etc . A junkbox or flea market
item.

Hello,

The following valves are for sale. They are unused unless otherwise specified, and mostly in original boxes. They are all in stock and can be shipped immediately to anywhere in the world.

2 pcs 3069M Large, round CRT in super heavy duty packing material each in a wooden barrel. One in

completely new, obviously never unpacked (only by me for inspection), the other one seems also to be new and unused but it has

been opened by someone. US$ 250.- each

8 pcs F16-10LD CRT by GEC (some boxes says 'Haltron' on the outside. I have not opened to verify). They

are obviously all unused. US$ 150.- each

1 pcs F16-10LD CRT as above, but made by Mullard. US$ 150.-

1 pcs F16-10LD CRT as above, but this one is used. It has a little spot on the screen. US$ 75.-

4 pcs 7BP7 CRT. The boxes says 'Haltron' I have not looked inside. Unused and unopened. US$ 100.- each

5 pcs 5FP7 CRT. The boxes says 'Haltron'. Some are opened and some are sealed. All the valves are

obviously unused US$ 75.- each

6 pcs P535/1E STC pulse modulator valve. Also coded CV 427. It is similar to 715C. All unused. US$ 50.- each

1 pcs P535/1E Same as above, but this one seems to be used. US$ 30.-

6 pcs C1148 EEV pulse modulator valve. Unused and in original boxes US$ 35.- each

12 pcs C1150/1 EEV pulse modulator valve. Unused and in original boxes US$ 38.- each

3 pcs C1166 EEV pulse modulator valve. Unused and in original boxes. US$ 40.- each

1 pcs QF 451 Ferranti. Looks like a radar TR switch and unused. US$ 20.-

1 pcs KS 9-40D Mullard klystron. Unused in sealed box US$ 20.-

4 pcs M509 EEV magnetron. Also coded CV 3982. Unused in
sealed box US$ 50.- each

2 pcs M599 EEV magnetron. Unused in sealed box US$ 50.- each

1 pcs JP 9-75 Mullard magnetron. Unused in sealed box US$ 50.-

7 pcs 24B1 STC trigatron valve. Unused in original box (Strange
looking valve) US$ 30.- each

11 pcs 725A Western Electric magnetron. Unused in sealed boxes.
US$ 30.- each

I bought a pint of toluene yesterday for around $4.00 at Fischer's Hardware in Springfield VA. (suburban Washington DC) Fischer's is quite a place, a hardware store about the size of a large supermarket but organized and stocked along the lines of a old time hardware store, not a Home Depot.

I bought "E-Z Toluene," from E.E. Zimmerman Co., Pittsburgh PA. It was available in pints, quarts and gallons at Fischer's paint department.

I went to our local small "old time" hardware store and didn't find it. However, the paint expert there said that Fischer's did carry it and he was right. He also said that the "big box" stores (Home Depot, Lowes, etc.) didn't carry it to his knowledge. I also tried Duron paint, but couldn't find it there either.

I used it to restore a bottle of mostly dried up Q-dope. I'm now going to dissolve a box of plastic peanuts to try some home made Q-dope.

I found 8 ohm to 1 K audio transtormers at RadioSchack and that'd be close enough to use between the two systems. You ought to include a 600 ohm attenuator between the transformer and the sound card, perhaps 6 dB.

I just picked 6 dB at random, since I am not sure as to the required drive voltage, but you can also include two back to back diodes across the input to the sound card. The attenuator would limit the current in the diodes when they clip voltage peaks, while the diodes would protect the sound card.

The more correct method would be to look up the input voltage specs for the sound card and then set the attenuator for the proper value.

Actually, none of the suggested solutions is optimal.

First, the level out of the scanner is way too high for the sound card. If you connect it diretly you will overload the sound card and potential cause damage.

Second, the scanner output will be very noisy if you turn the gain down low enough to avoid overdriving.

Third, you probably should put a load on the scanner so it will operate optimally, anything over 8 Ohms and less than 100 Ohms probably would be fine.

The best place to get audio out of the scanner is from an earlier audio stage. However, many units use integrated amplifiers and it might not be trivial to create a line output, but you can start by using the signal at the high side of the volume control.

If you don't want to modify the scanner, build a simple attenuator on the speaker output, which will be about three Volts if you have one Watt into eight Ohms. Drop that to about 1/4 Volt, about 10 or 12 to 1 reduction with a little divider, which can also provide the termination mentioned in Third, above. Use, say, a 100 Ohm resistor in series with a 10 Ohm resistor to ground at the scanner output. Use the signal at the 10 Ohm resistor to go to the sound card, but for safety sake I'd put a 1k resistor in the line to the sound card.

3853. Re: Basic surge arrester circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-29 16:56:39 UTC
From: w_tom <w_tom1@usa.net>
Message-ID: <3CF50847.CDA77E4@usa.net>
Source record: 43894

In each case cited, a non-destructive path to earth is established. The tower surge protector provides lightning with a path to earth ground that does not pass through the repeater. Low impedance devices not just create equipotential across the repeater. No such equipotential could exist if lightning did not have a path, not through repeater, to earth ground. The equipotetial exists because lightning has a better path around the repeater than through it.

In each example cited, shunt mode surge protectors provide lightning with a path to earth that does not pass through the protected equipment. Normally we accomplish same by directly connecting to earth ground. But not all wires can have such connections and operate. So we install surge protectors to make a temporary shunt to earth during the surge.

Another effective component are filters - series mode protection. They make a path to earth ground less desirable. However without that other, better path to earth directly or through a shunt mode protector, then filters (ie inductors) cannot be effective. Without that other path to earth, then voltage confronting the filter would exceed the filter's breakdown voltage - short across the inductor. So and again, even filters are dependent on lightning having a better path to earth so that protected electronics will not be damaged.

Earth is what the CG lightning bolt wants. It will obtain that objective no matter what is put in its path. Effective surge protection diverts lightning by providing a better, alternative path to earth ground. Lightning seeks earth ground. No surge protector can change that. It is why effective shunt mode protectors are defined by their earth ground; albeit MOVs, GDTs, or spark gaps.

Making a device equipotential or essence a farady cage is another perspective of the issue. However, the lightning bolt still must have that earth ground path. That aspect cannot be avoided. When designing surge protection for complex devices such as aircraft, what is earth ground? Earth ground exists. It just can vary with each event. Lightning strikes the nose and leaves on the left wing. The left wing is the earth ground connection. It strikes the right wing and leaves on the tail. The tail is earth ground in that analysis. Aircraft designs for surge protection are that more complex.

But a tower is quite easy. If the MOV provides a better path
around the repeater, then the repeater is not damaged. But
that is all a shunt mode surge protector (MOVs, GDTs, etc)
does - connect the surge to earth ground through a
non-destructive path.

What bandwidth do you need?

There are stock 10.7 MHz crystal filters available for VHF FM type receivers. Digikey is one supplier that carries them, and the price is reasonable.

Bandwidths are dozens of kHz, as used in 146 or 440 MHz receivers.

It's also a bit strange that by this formula, the inductance,
apparently, depends linearly on the winding pitch. Coils whose pitch
I've had the good fortune to adjust seem to decrease in inductance as
the pitch increases.

Cross-posted to:
rec.radio.amateur.homebrew,rec.audio.tubes,rec.audio.marketplace,rec.radio.amateur.boatanchors,rec.radio.amateur.equipment

Hello,

PC 900 is a B7G base triode with a heater of 3.9V 0.3A, Va is 135V
Vg -1V Ia=11mA Wa 2.2W Ik=20mA max, u=76 and the gm is 14.5mA/V
A very promising valve to experiment with in low-level stages, both
audio and HF/VHF amplification. It was developed for use in VHF and
UHF television tuners. The low heater voltage makes it very easy to
use in an ordinary 6.3V heater system, just use a dropper resistor of
8.2 ohm 2W and you are very close to 3.9V

I have 400 pcs in stock and I will sell them at only $ 5.00 each or
$ 2.50 each if you buy 100 pcs or more. The valves are NOS, in mint
condition, original boxes and the label is Haltron. but they are
rebranded, and I think they are originally made by Philips or Siemens.
E-mail me if interested.

Best regards,

Arnold Goks&#65533;yr

w_tom wrote:
>
> Surge
> protectors don't stop or absorb surges.

Assuming sufficient magnitude and duration of the surge
across the MOV terminations, an MOV type surge protector
will absorb the surge at it's terminals up to the point
where the protector blows - sometimes violently. If it
did not absorb energy, how did it blow?

Assuming sufficient magnitude of the surge at the mov
terminals, the mov will switch from extremely high
resistance to low resistance. Current will flow through
the MOV and cause heating in that resistance. The MOV is
absorbing energy from the surge and converting it to heat.
It can only dissipate so much of that before it blows.
There's no escaping ohm's law.

> That is urban myth.

No. It's physics.

> A surge protector only connects a surge to earth ground.

No, an MOV type surge protector connects a surge it "sees",
through its own internal resistance, to the places where the
leads of the MOV connect.

>It is
> only one 'system' component. No earth ground means no
> effective surge protection.
>
> Effective surge protectors shunt (short, connect) each wire
> to earth ground during the surge.

If you are talking about MOV's in the above, it is not true.
The MOVs do not short the wires to ground. They connect, or
shunt the wires to ground through a variable resistance. If they
shorted them to ground, the clamping voltage rating would
not exist. The metal oxide varistor changes its resistance
such that sufficient current flows to create a voltage
across the MOV terminations equal to the clamping voltage
rating.

>Therefore wire length to
> earth ground is also an electronic component in your 'system'

> schematic. A surge protector is only as effective as its
> earth ground.

Not true. A surge protector that has no connection
to earth ground can still lessen or eliminate a surge
between two wires to which it is connected.

I'd suggest using ECS monolithic crystal filters from Digi-Key
(http://info.digikey.com/T022/V5/0491.pdf). They are only a few bucks
apiece, and they can give you 3 dB responses at +/- 3.75 kHz, +/- 7.5
kHz, and +/- 15 kHz. These are ideal resolution bandwidths for a
non-stabilized spectrum analyzer, since anything narrower won't be very
usable.

The ECS filters can be matched to 50 ohms with a simple L network (a 6.8
uH series inductor and 20-50 pF parallel trimmer at each end, in the
case of the 3000-ohm parts). And they can be cascaded with no problem.
Last weekend, I built an 8-pole IF filter with two ECS-10.7-15B parts.
It had less than 2 dB insertion loss, +/- 0.5 dB passband ripple, and
almost 90 dB of loss at my image frequency (9.790 MHz). A 1 mH choke to
ground between the two filters was all it took to flatten out the
passband.

I found that the ultimate attenuation seems to be limited more by the
input and output matching networks' tendency to "talk" to each other
despite lots of shielding, than by leakage in the filters themselves.
It would probably be possible to do better than 100-110 dB with the
right layout.

These are really great parts.

That won't happen. A speaker output that delivers 0.5WRMS into 8 ohms
and the typical line-level source for which your sound card was designed
will both be in the 2-3V RMS range. The only difference is that the
speaker output has a lower source impedance.

> Second, the scanner output will be very noisy if you turn the gain down low

See above. You won't need to turn the gain down as much as you think.

> Third, you probably should put a load on the scanner so it will operate

True, as noted previously.

> The best place to get audio out of the scanner is from an earlier audio

Also true, when it's practical to do so. But far from mandatory.

I've run the speaker level output of a receiver directly into the line input on the sound card numerous times and found the levels about right. Sound card mixer about 1/3 up and receiver set to comfortable listening level with speaker attached.

If you only have a mike input on the sound card then you'll need about a 100 to 1 attenuator to get the speaker levels down to the required mike level inputs.

The other thing that has worked for monitoring is to just set the lap top computer with internal microphone activated near to the receiver speaker.

I had some MEK (methly ethyl keytone) in the garage. I picked it up
at the paint store in California not too long back. It's described
as, "similar to acetone but dries slower". This may be a reasonable
alternative.

I poped some penuts in a small amount and it gobbled them up. I
haven't tried it yet. When I do I'll post again if there were
problems, otherwise assume it worked.

Source record: 43810

Thanks for all the post! Some good ideas in there.

Let me explain why I'm looking for 10.7MHz stuff...

I'm looking for crystals that are 10.7MHz to
make a filter from a idea I seen in Electronics World
magazine (June 1996). It uses 1 crystal per stage for a total of
4 stages. Each stage uses a PIN diode to vary
the bandwidth of that stage. The ideal crystals for this
operate in series fundamental mode, has identical frequencies, and a
minimum equivalent resistance. The more ideal the crystals to
this specification, the narrower the IF stages will be.

To answer the question "why 10.7MHz"?
I'm going to use a Log detector circuit from Analog
Devices that incorporates the AD603/AD8307 in a
circuit that uses a Murata 10.7MHz ceramic filter (which I have)
that has a smooth bandpass characteristic (very little ripple).
I'm not married to 10.7MHz but it seems likely I'll find more
10.7 crystal filters that I can dig the crystals out of and come
up with a matched set easier and cheaper than buying new crystals.

I also have several ceramic filters for 10.7MHz of various bandwidths
that I plan to use if this circuit don't pan out. I may not need these
at all if the crystal IF amp checks out okay (fingers crossed!).

I think my best bet at this time is finding a few crystal filters from
VHF/UHF business band radios, open them up and find 4 closely
matched crystals. I know there are probably many of those floating
around, if I can find the right person or business who has them.
Anyone have any they would sell me??? Let me know!

Thanks for all the help and don't stop now if you have different ideas
to share. I'm still open to different ways to making variable bandwidth
IF amps.

Thanks again!
Mark M.

Source record: 43811

To say an MOV absorbs surge energy is to say wire protects by absorbing a surge. In a properly sized surge protector, many times more energy is diverted through a shunt mode surge protector than is absorbed. It is not the function of a shunt mode surge protector to absorb energy. It's job is to divert - shunt - energy to earth ground. Like a wire, the MOV is not perfect. Like a wire, the MOV will absorb a minor percentage of the surge. But if the surge is not provided that shunt to earth ground via the MOV, then the surge may find a path to earth destructively through an appliance.

The purpose of shunt mode surge protection is to shunt - short, divert, connect - the surge to earth ground. A better shunt mode surge protector is defined by the even less energy absorbed - just like a better wire is defined by less energy it absorbs. But the function of both wire and shunt mode surge protector is not to absorb or stop a electrical energy.

> A surge protector that has no connection
> to earth ground can still lessen or eliminate a surge
> between two wires to which it is connected.
Only true for differential mode surges which typically don't exist. Destructive surges are typically common mode. Distributing a common mode surge between wires at the appliance will not provide effective protection. But even worse, a shunt mode surge protector can even contribute to damage of an adjacent powered off computer - because the surge protector is too close to transistors and too far from earth ground. All but no earth ground means no effective surge protection.

I am thinking of building an HF Amp. I was thinking of using 2 Gu74b's the Russian 4cx800a because the price on these tubs seems very cheap.
I would like to know if any one here has any experience with these tubs?
I've herd some good things about them and some bad things. I don't want to waste my time with them if there not up to scratch. The Amp will be mostly used for SSTV.

Thank you
Jerry

That's correct.

>It is not the function of a shunt mode surge protector to absorb
>energy.

Well, not the *main* or intended function. Mostly it's an unwanted inefficiency - it would be far better if the surge protector was 100% efficient at diverting, so there was no risk of its being destroyed by energy absorption.

> It's job is to divert - shunt - energy to earth ground.

Here's where we part company. Your insistence on saying "to earth ground" results in bizarre statements like "The left wing [of an aircraft in flight] is the earth ground connection." It may be the kind of language that specialist avionics EMP engineers might use among themselves, because they all know what they *don't* mean, not really... but the rest of the engineering world quite rightly goes "Huh?"

(Somebody ought to do a linguistics PhD on 'The Deliberate Misuse of Normal Language as an Initiation Ritual into a Closed Workgroup.' Heck, they probably have already.)

It's far better to think and talk about diverting unwanted energy *away from* the equipment you want to protect. That gives you a consistent way of thinking which applies to all kinds of systems. It doesn't much matter where the diverted current flows away to - what matters are the potential differences experienced inside the equipment, because those are what do the damage.

The objective is to make sure that all the target equipment - all the chassis frames and every connected port - stays at the same potential. It doesn't matter what that potential is. It's free to "bounce" relative to other parts of the system, so long as that doesn't lead to an insulation breakdown which creates a new connection and a new current path.

For any analysis, you need to define a voltage reference point, and that really needs to be a well-defined location close to the equipment. The farther away you go from the target equipment, the harder it is to understand what might happen.

In BC transmitter systems the voltage reference point is usually the metal plate through which the feeders and all other services pass. This plate also has a very good connection to Planet Earth, but the so-called "earthed" end of the connection would not be a good place for the voltage reference, because large and hard-to-quantify potential difference can be developed along the conductor and within the earth itself.

In an aircraft, the voltage reference point can be the left wingtip if you like, but there are probably better choices, closer to the equipment. It certainly does not have to be the place where the lightning departs.

But wherever it is, please don't call it "earth ground"!

In most cases there is no need to match impedances between the speaker output and the sound card line input. All you need is enough voltage from the speaker output. It does no good to use a transformer which steps up the voltage and then turn around and reduce it again with an attenuator. With any normal sized receiver (5 watts or so max output), a direct connection between the speaker and the line input will work just fine.

I've used the output from my FT102 directly into the sound card input of
my laptop (Compaq Presario) for PSK31 and so far have had no problems.

The following web-site gives various options for the connections:

http://www.w5bbr.com/soundbd.html

All the best

More in the ongoing Q dope saga,

I got some packing peanuts which did not dissolve in water, so I figured they were poly (and not starch). I then poured about 1/4 of an oz of fingernail polish remover (mostly acetone according to the label) into a glass dish, and started feeding it peanuts. After about 200 peanuts I realized this was not working. The peanuts (some of which I shredded, and some not) simply shriveled up to about 1/50th their size, but the liquid remained unchanged. It did not get thicker, or sticky.

So.......my next attempt will be to get some *pure* acetone and try it again.

BTW, the fingernail polish remover *did* bring the jello-like Q dope back to a fluid state, but it is now a milky white color instead of the original crystal clear (maybe due to the other stuff in the remover?). I have not yet tried it on a coil to check it's holding properties.

More anon.......

I tried the MEK with styrofoam peanuts and it seemed to work fine. I
dissoved a bunch of peanuts in about a tablespoon or two of MEK
until it got a bit thick.

As expected the MEK evaporates not as fast as acetone would. I
expect it would be a little less likely to attack things it was
painted on too.

You may find MEK is actually MORE likely to dissolve things it is put on, such as plastic coil forms. MEK is one of the most powerful solvents there is, so use it with caution.

In the days before heat shrink tubing, it was customary to soak plastic tubing in toluene for several hours to make it expand, then put it on the joint and it would shrink down as the toluene dried and make a tight covering. One day we tried MEK just to see what would happen and it completely dissolved the tubing. Nasty stuff.

My guess is that you won't want to use ceramic filters in a spectrum analyzer. They have terribly-jagged spurious responses all over the place. They're really only good for use in WBFM receivers. SAW filters would probably be a better choice for your wider RBWs.

Also, unlike in a communications receiver, an incrementally-variable IF bandwidth isn't especially useful in a spectrum analyzer. It's nice if you can get 1/3/10 steps, but even decade steps are fine for most purposes. Some of the most popular surplus models from Tek only offer 1 MHz/100 kHz/10 kHz/1 kHz choices with 100 Hz available optionally, and we're talking about instruments that cost $30-$50K new.

It's much better to use a few high-quality filters with good shape factors and freedom from spurs than to worry about any type of variable-bandwidth hack that might compromise the important specs.

For lightning surges, it is better to observe the entire circuit from farther back. In surge protection, that circuit must include the cloud and a region of earth containing opposite polarity charges. This location of charges is typically not at the CG strike location. The part of the circuit that includes a structure's earth ground, incoming utility wires, and building appliances is but a small part of the bigger circuit.

Defining the "airplane's left wing" as earth ground is only to compare aircraft surge protection to structural surge protection and demonstrate the greater complexities of aircraft surge protection. From the perspective of an aircraft surge protector, where that surge must go to complete the circuit changes with each event. From the perspective of flight critical equipment, the surge's outgoing path (what is simplified into the aircraft's earth ground for that event) can vary with each event.

That lightning bolt that exited on the left wing then continued on to earth ground. Therefore, in simplistic terms, that left wing was the airplane's earth ground - the reference point, but only during that event.

The concept of surge protection, such as a faraday cage, is to make the equipment (or structure) equipotential. But in reality we cannot do that. No material is conductive enough. Even for monolithic, all aluminum airplane skin, potential differences exist across the aircraft. Yes, we try to make the building equipotential, such as make the entire ground under the building equipotential. But in reality that is insufficient because we can never make that underneath ground equipotential.

So we attempt to divert (shunt) a surge into a single point ground so that the surge does not approach equipment. But we can never make that central earth ground conductive enough. The entire surge will never take that earth ground path. The diversion path is insufficient because it can never be made conductive enough. To surges, wire is another electronic device.

IOW surge protection is about doing both concepts so that each will compensate of the inadequacies of the other. Central earth ground connected to the best conductive earth under the building, and even better, using an existing Ufer

ground available in most building today makes surge protection
more effective.

Yes, we want to make the underlying ground equipotential AND
we want to divert ae surge to earth before it gets near to the
appliance. We do both with a good, central earthed ground
surge protection 'system'. But since typically destructive
surges are common mode, then earth grounding is essential to a
surge protection 'system'.

What would you like to call that ground rod and other
interconnected conductors in the earth? Central ground?
Equipotenial ground. Most here only know that rod, to which
all incoming utilities (should) connect, as the earth ground
rod. This has been called earth ground, which is connected to
but is different from breaker box safety ground, which is
connected to but is different from motherboard ground. What
would be a better expression for 'earth ground' that every
homeowner would understand?

3882. Winding the Univeral Wound Coil Question - Gingery Coil Winder

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-30 18:11:31 UTC
From: Jack Smith <jsmith@mnsinc.com>
Message-ID: <dvocfucso1iir41vf8hf7d0nv219co66a1@4ax.com>
Source record: 43824

I've recently finished building the "Gingery Universal Coil Winder" as per the pamphlet written by Dave Gingery. For those unfamiliar with this gadget, it is a home shop buildable version of the old Morris coil winders that alas have been out of production for 20 years or more.

You can see a drawing of the Gingery coil winder at: http://www.lindsaybks.com/dgjp/djgbk/coil/. The idea is that as you turn the crank, coil form revolves (it is held between the two cones) and the wire guide (the part that is shown as touching the spindle between the two cones) oscillates back and forth. This gives a crossing pattern to the windings. The cam that causes the oscillation is a simple off-center circle, so the resultant pattern will be sinusoidal.

Now comes the fun part--winding some coils. Here, however, I'm not as successful as I thought I might be.

My first problem was the first few windings would slip on the coil form. I more or less solved that problem dissolving some musician's rosin in denatured alcohol and painting the coil form with the solution. After the alcohol evaporates, the coil form is left with a sticky coat that reduces wire slippage to an acceptable degree.

What I'm having trouble with is getting a nice square topped winding. Instead, I see something that looks more like a gentle hill. As the wire oscillates back and forth, it will track for a while long one side of the center and then the other side. I've experimented with the length of the wire guide and what I've found the best is for the end of the guide to be spaced about 3/8s or 1/2 inch from the surface of the coil form (coil form is a 1/4 inch diameter paper tube). In this case, the tension of the wire holds the wire guide at a slight angle below horizontal. (The design of this winder is that the wire guide is supported only by the tension of the wire; it is free to rotate on the oscillating shaft.)

My samples use No. 34 AWG (0.006 inch diameter) enameled magnet wire.

I've also found that gently touching a small brush with the rosin/alcohol mixture to the wire as it feeds onto the coil form helps a bit as it increases the friction between wire layers.

The ratio between coil revolutions and oscillations is variable, over a range of 0.9 revolutions per oscillation to around 2.0 revolution per oscillation. Based on the design of the 2.5 mH choke, I've set the machine for around 0.9 revolutions per oscillation.

I'm hoping someone out there has built the Gingery winder, or has a Morris winder (assuming it uses the same system) and can offer some suggestions, or confirm that perfection isn't possible with this simple machine, at least with enameled wire.

A related question is that all the commercially made universal coils in my junk box (such as the ubiquitous 2.5 mH choke) seem to use wire insulated with fabric (silk? cotton?) that has much more turn-to-turn friction than possible with enamel led wire. This may be the source of my problem, and in fact, the brief operating notes in Gingery's pamphlets suggest cotton covered wire best performance. Anyone have sources for small, say 34 AWG to 28 AWG or so, fabric insulated wire? All I can find is hookup size fabric insulated wire.

By the way, I measured the wire diameter (copper only) on a defective 2.5 mH choke as 0.0062 inches, so no. 34 AWG is about the right diameter.

You hit the nail on the head. Cotton Covered or Double Cotton Covered wire works best for Pi wound coils. Finding it isn't easy - especially in small quantities. It is still widely used in the pipe organ industry, so you might try someone like Peterson Electro Music, or Organ Supply Industries.

I've just had some interesting and informative email correspondence with Sylvan Butler, N7OWL, about gelled vs absorbed-liquid (AGM) sealed lead acid (SLA) batteries. I had commented that batteries with gelled electrolyte are rare, despite the fact that amateurs call all SLA batteries "gel cells". Sylvan had disagreed, saying that gelled types were common and AGM types rare.

This, and our correspondence, prompted me to do some web searching, and I came up with the following:

One of the batteries I see very often is the Panasonic SLA. Its electrolyte system is described at http://www.panasonic.com/industrial/battery/oem/images/pdf/slaover.pdf. It's pretty clearly AGM type and not gelled.

Sylvan and I both agree that one of the most common SLA batteries encountered is the Yuasa NP series. He had taken one, or a similar battery, apart and found gelled electrolyte. But Here's what the Yuasa web site says about the NP series, at http://www.yuasa-battery.co.uk/NP_Batteries.html:

"All NP batteries utilise Yuasa's unique electrolyte Suspension system incorporating a microfine glass mat to retain the maximum amount of electrolyte in the cells. The electrolyte is retained in the separator material by miniscus effect and there is no free electrolyte to escape from the cells. No gels or other contaminants are added."

The vent is described:

"The batteries are equipped with a simple, safe low pressure venting system which releases excess gas and automatically reseals should there be a build up of gas within the battery due to severe overcharge. However, on no account should the battery be charged in a sealed container."

I downloaded the Yuasa NP manual. It uses slightly different wording to describe the electrolyte system:

"All Yuasa NP batteries utilise an electrolyte suspension system consisting of a glass fibre separator material. This suspension system helps to achieve maximum service life, by fully retaining the electrolyte and preventing its escape from the separator material. No silica gels or other contaminents are used."

So it's clear that the common Yuasa NP series is also AGM and not gelled electrolyte type.

In email, Sylvan commented:

I agree.

But I do know I've taken apart several defunct SLAs and found a pudding-like substance (usually visibly dehydrated and cracking) inside, under the epoxy or tar seal.

Looking at the www.yuasa-battery.co.uk site, they only mention AGM types of SLAs. They also refer to their "NP" family as "a new generation". I wonder if they used to sell gelled electrolyte a few years ago, but now are not?

There are a lot of advantages of AGM compared to gelled, so discontinuing gelled and replacing them with AGM would not suprise me. The only disadvantage would be cost, and that may be somewhat mitigated if (as some nations require) the manufacturer is accounting for end-of-life recycling.

--------end of comment-------

With at least the popular Panasonic and Yuasa types not being gelled, I'll stand by my statement that truly gelled electrolyte SLAs are uncommon, although they certainly do exist. Does anyone know of a relatively common type of SLA that really does have gelled electrolyte?

Maybe one lead for external antenna; one lead for rf amp; one lead for
oscillator; one lead for common?
It's impossible to tell what lead is used where! An inductance meter
would tell you the various inductances; other than that, who knows. That
ferrite coil was no doubt made for one specific brand and model of
radio.
(I had to check the date to make sure my computer wasn't telling me
April first!)

It's a good bet that the commercial chokes use Litz wire, possibly
with a fabric wrap. This gives higher "Q" at MF and low HF
frequencies. The irregular surface helps hold the turns in place.

Be careful with any coil dope you apply to Litz. It's made to be
chemically or thermally stripped, so the coating can be damaged by
many solvents. Check for compatibility before winding!

Buying Litz in small quantities isn't easy. Try unwinding an unwanted
or broken junkbox part if your needs are small. This works best on
parts that are finished with wax, not varnished ones!

Good luck,

I've been reading this thread with great interest. I now know how to make home made Q-Dope and how to recover the stuff that has gelled up and is unusable. Please tell me, however, because I don't know: What are the intended uses of Q-Dope?

I've heard of and actually used General Cement's "corona dope" to fix arcing flyback transformers in old color TV's, but have never heard of Q-Dope!!!

Thanks and 73.

You might want to try Charles Days at oldradiodays@attbi.com for Litz wire. He was recently juggling his email address so if that one bounces post a note for him on rec.antiques.radio+phono.

It is used to 'paint' over the windings of a coil to secure the windings to the form. I believe the "Q" comes from the fact that once dry, the coating has little loss at RF so as not to degrade the Q of the coil (Ratio of reactance to resistive loss).

Source record: 43834

Hi Group,

I am looking for a 10.7 MHz IF filter also, however I need a 2 MHz bandwidth. The largest bandwidth I have found to be in the FMBC receivers at about 200KHz.

Is there a method to reduce the Q or whatever in the 10.7 MHz 200KHz filter so that it increases the -3db BW to 2 MHz?

How about a two crystal filter with Lower freq crystal at 8.7MHz and Upper Freq at 12.7 MHz ?

How about a discrete(L/C) or active (op-amp) filter?

Others????

Thanks,

Paul

: > (3-5 years) in my "shack" as they do in my automobiles.
: >
: > --Myron.
:
: I've been using them for nearly 15 years here and no problems. Car
: batteries hold up fine as long as you don't overcharge them, don't let
: them discharge too far, and keep the water up in them. But I do prefer
: a marine deep cycle if I had my choice as their design suits radio use
: better. But a car battery will work just fine. I'm running a 706 on
: one right now. I use a fully automatic charger to keep the charge up,
: but a trickle charge will work fine as long as you remember to unhook
: it when you have a full charge. Heavily discharging a car battery will
: greatly shorten it's life and capacity. All long as you avoid that,
: you won't have much trouble. A deep cycle can handle heavy discharges
: better, but even with those it's best not to heavily discharge them. I
: never heavily discharge any of those lead acid batteries on purpose.
: Sometimes it'll happen though out portable etc. If I buy a new battery
: just for radio use, I get the big marine deep cycles. MK

Here's my experience:

I find that I have had to replace stock Automotive starting batteries
about 2:1 when compared to Marine Deep Cycle batteries.

I have had good life with Gates cells even though I have only bought
used ones. All of gells (or whatever) are pulls from UPS service, and
either they are good and I get a few years use or I pitch them. I have
a couple that claim to be sealed that didn't have as much life as the
```

sealed Gells (says "GELL" on the side) that were 5 years old when
I got them.

Currently I have 7 years on a Nautilus group 27 Deep Cycle Marine
in the trunk (in a box with a fusible link) that pulls all the radio gear
with the key off and has still outlasted 2 "premium" 72 month batteries
in the front of the vehicle. Before I went to dual systems my battery
life on the front OEM and Premium batteries was even worse. Even
when I was buying the best that could squeeze into the space.
I can't count how many Die Hard and JCPenny batteries I fried when
I was running around with Motracs in the early days. If only Radio
Shack had them on the "free battery a month" cards along with
"lifetime" tubes.

> mode surge protector to absorb energy.

(Ignoring the first sentence. As will be shown, wire
does absorb surge energy.) That's much better.
Now lets put it into a bit more detailed perspective.
First, consider the circuit as three elements: the path
from the source to the mov with impedance Z1, the mov
itself with impedance Z2, and the path back to the source
with impedance Z3. Total power dissipated at any
instant in time is equal to Isubt^2*Z1 + Isubt^2*Z2 +
Isubt^2*Z3. Z2 varies in the presence of a surge, causing
I to vary, so the term Isubt. We can also look at the circuit
in terms of voltage. The voltage drop across Z1 at any
instant is Isubt*Z1; the voltage drop across the Mov
is Isubt*Z2 (which, during a surge, is the clamping voltage)
and the voltage drop across Z3 is Isubt*Z3.

Now, lets use some numbers. We'll use an MOV with a
clamping voltage of 300 at time T, and specify a surge
of 1,300 volts at time T. We'll specify a run of
25 feet of #12 copper, at 2 ohms per 1000 feet, from the
source of the surge to the MOV another 25 feet of #12
back to the source. Thus each of those wires will have
.05 ohms impedance. Now, since we know the MOV will
have a 300 volt drop across it at time T, we also know
that we need to drop 1,000 volts across the impedance of
the other two elements. Their combined impedance is
.1 ohms. That means that, at time T, the current is
10,000 amps. For 10,000 amps to produce a 300 volt
drop across the MOV, its impedance must be .03 ohms.
The power absorbed in the first wire, at time T is
500 volts times 10,000 amps - the same as the power
in the second wire. The total is 10,000,000. In
the MOV, the power is only 300 volts times 10,000
amps or 3,000,000. Physics dictates that a current
flowing through a resistance causes power to be
absorbed by that resistance.

Now, consider what the MOV sees: the voltage at its terminals, and the current through itself. That voltage is 300 - 500 was dropped across Z1, and 500 was dropped across Z3. The current was computed to be 10,000 amps. So the MOV "sees" 300 times 10,000, and it absorbs that, or dies trying to. Meanwhile, exactly what you said is happening elsewhere in the circuit: many times more energy is diverted elsewhere than is absorbed in the MOV.

> It's job is to divert
> - shunt - energy ...

Its job is to clamp the voltage to some specified level. It does that by changing its internal resistance from very high to very low when the voltage it "sees" rises above some specified level.

> ... to earth ground.

Earth ground may not be involved.

If you can find an old Comdel CP11, they were an excellent processor.
Plugs in between mike
and audio in on the rig. They convert the audio to SSB, clip it,
filter it and convert it back to
audio again. So it gives the benefit of rf clipping but is in your
audio chain.

Ahem, IMHO, the best one is the one I designed.

See: http://users.triconet.org/wesandlinda/s_proc.pdf

for my paper which was published in Ham Radio Magazine Sept 1979.

There is a remote possibility that I can scrounge up a board for the clipper/filter for this project. The Plessey chip is long obsolete so if you would like compression ahead of the clipper, you would need an alternate circuit.

Once upon a time this was offered as a kit by a company that stole the design from me, but they went belly up a long time ago.

You didn't state the slope you want. A filter that wide can be implemented with a few low Q tuned circuits. Crystals are inappropriate for such a bandwidth.

Perhaps you'd best design a low pass at 11.7 and a high pass at 9.7 MHz and cascade them. That can be a simple enough filter in each case; if you need steeper slope you can cascade a few like sections.

This is a very clean example of the Mizuho SX-59 solid state preselector which was sold in the U.S. by Gilfer Associates in the late '70's. It will really punch up the sensitivity and help reduce images in many older ham and shortwave receivers, especially the tube types that seemed to run out of gas above 20 meters. It has an internal relay that can be remote-controlled for transceive operation
I will include the data sheet, operating instructions and manual with this purchase.

Thanks again for looking.

Good Morning Bruno. You can purchase the 3125 by a number of manufacturers from Digi Key. Price is about a dollar for single quantity. They do have a $25 minimum order to get away from the surcharge, so pick up something else you need at the same time. Maplin in the UK sells them, as does a supplier in the Netherlands, but the one in Holland wants $5 EACH for them.

The device is good for about +41, +42 in Ip3 tests I've done with square wave LO. Add a few dB for input filter losses and you're right up there with your desired +45.

Hi Marvin,
try to specify, whether all four leads belong to one coil or two
separate coils. Use an ohmmeter. If there are two coils, the "bigger"
one (i.e. more turns, bigger inductance and, probably, bigger
resistance) connects to the variable capacitor and the other one is
coupling to the RF amplifier or mixer. If there is one coil only, then
the section with least turns is probably the coupling lead and the
other two leads are switched to the variable capacitor for MW / LW. Or
there may be a coupling lead for an external antenna, too.

Best regards from Ivan

Hello,

I have several of these antique globe shape German triodes in stock.
It is directly heated, and has an European 4-pin base and about 12W
anode dissipation. The heater is 3.8V 0.72A, u=17, S = 3.0mA/V Max.
anode voltage is 400V.The valves are NOS, and very nice to look at.
You will find a picture at my web site. www.demostenes.no
Just search for RS 242 in the left hand corner.
Please contact me by e-mail if you are interested.

Hi,

A few years ago I read an article in a magazine about some guys who apparently had way too much time on their hands, so they decided to see if it was possible to make a working electron tube using a beer bottle for the casing.

It did work, after a fashion. That I remember. I was, however, unable to find any references on the web; does anybody recognize this plot? If so, would you be so kind as to point me in the right direction? Any web links are most welcome.

Thanks,

I saw one of the on ebay a while back. Almost bid on it just to "check out the competition." <g>

|
|Ham Radio was the best ham radio magazine bar none. It was rich with
|good technical articles. I have all issues from the first to the last,
|but I am keeping them, I still pull a couple of issues once in a while
|to just read the articles which are more interesting than what we get
|now. I remember the very good split band processor article. I can't
|remember the name of the company that built those but I think they were
|marketed by Alpha for a while. I'd have to look in one of the HR issues.

Maximillion Associates built a commercial split band processor.

After my article was published, I was swamped with requests for a source of circuit boards. I wasn't in the board business but I got so many requests I went to a local company and ordered a minimum run of 100 sets.

I had no soon committed to this than a letter arrives from a company called Circuit Board Specialists. The letter included a set of boards and informed me that they had had so many requests that *they* were going to offer boards for sale. Since the boards had both *my* call sign and the hr logo on them I called Jim Fisk, the founder and editor of hr magazine.

I asked him whether he had a problem with copyright and he replied that he had no objection; and "Oh, by the way, there is a kit coming out for your design." What he failed to mention was that the kit was the first offering from a new company named Radio Kit, that he just happened to own. The kits apparently were in work before the article was published.

I wound up paying for a small classified ad in hr and sold out the first run of boards as well as a follow up order. They literally when around the world. I actually had a request from a VK4 nine years after publication.

BTW, my (and everybody else's) Kenwood TS-870 uses a split band speech processor.

3912. Re: Basic surge arrester circuit?

Newsgroup: rec.radio.amateur.homebrew
Date: 2002-05-31 16:40:52 UTC
From: gaschafer@attbi.com
Message-ID: <3cf7a836.5581110@netnews.attbi.com>
Source record: 43755

You are forgetting that with an MOV that has a turn on voltage of 300 volts, the equipment that
it is across is handling the first 300 volts and the MOV is dissipating zero at that level. It has not
yet turned on. When it does turn on that leaves 1000 volts to be divided up among the circuits.

But the DC resistance in the circuit is almost insignificant compared to the impedance from the
inductance of the length of the wires. So the MOV when conducting does present a very low
impedance compared to the rest of the circuit. The voltage across it is not going to go much
above the 300 volt turn on level so it does not dissipate much power. Not to say that they can't
blow up from excessive dissipation.

What W-tom is trying to say is that without a short ground lead it is almost like not having a
ground at all. This is of course concerning common mode type surges (lightning). Which does
need to be passed to ground.

In a differential mode (between 2 power leads example) no ground is needed as the energy is
not referenced to ground but between the two wires. These kinds of surges are not usually from
lightning but may be from other equipment on the power line etc. These types of surges will
usually have much less energy than lightning generated surges.

Concerning an airplane getting hit by lightning, who says that it needs to exit the airplane? The
airplane itself as a whole can be ground (flying earth). An airplane getting hit while in the air is
the same as lightning going between two clouds. That charge never ends up on earth. The
charge gets equalized between the two clouds. (cloud to cloud lightning) Not to say that a
lightning strike on it's way to earth couldn't hit a plane on it's way.

The way to do this is to look back before crystal and ceramic filters
were common.

If there was a need for such a wide IF, it would be supplied by
a string of IF transformers, usually spaced out between IF stages.
Early FM broadcast receivers would do exactly this. If the bandwidth
was too narrow, they'd either load down the IF transformers with
resistors to broaden the response, or move to a higher IF where the
bandwidth was easier to get, or sometimes both.

Back then, such a broad passband was either through calculations
you didn't see in the amateur books, or was haphazard. Now, you
might want to look at the sections of the books that deal with
fixed front-end filters; since people have done this sort of
thing, to do away with a preselector tuning, I'd say the information
is now more readily available. But of course, the wider the passband,
the harder it may be to get it nice and flat.

Ceramic, crystal and active filters tend to be solutions for narrow
band filters. It wouldn't make sense to start with such schemes,
and then try to broaden them, when even something like a string
of IF transformers might not easily offer up 2MHz of bandwidth.

You might want to look into SAW filters, though I don't know if they'd provide 2MHz bandwidth or be available at 10.7MHz. The only place I've come across them is in TV sets and VCRs, where they supply a 6MHz or so passband in the 40MHz range.

One thing about design is that it's the end results that are important, not specific points. So unless you offer up why this filter has to be at 10.7MHz, or perhaps even what you need a 2MHz passband for, finding a solution may not be so easy. Moving to a different center frequency might make sense, except if there is a good reason for it to be at 10.7MHz. Remember, one could always do a conversion from a higher frequency, if necessary.

I'd suggest an L/C filter, depending on your
ultimate rejection characteristics and shape
factor you'd probably do 3 or 5 sections.

Agreed. Here are some places to try. I've bought it
from the last one listed - American Science & Surplus.

In repeated studies of aircraft lightning strikes, there was always an incoming and outgoing point. Identifying that path is always part of the investigation into lightning incidents on aircraft. For example, when a Turkish Air Force 747 was struck on takeoff from Spain over the Atlantic in 1970, I remember the entry point as being the nose and exit was the left wingtip. The explosion was a result of currents passing through where the left wing meets the body - a design weakness.

In a two man experimental glider flying north of London, the entry point was the right wing tip and exit was the left wingtip. In that case, the carbon fiber strut carried most of the current but caused fatigue to the strut. In that case, both pilots, rather dazed, managed to recover and escape using parachutes.

But the point is, even in aircraft strikes, there is a current from from the incoming to outgoing point.

A video demonstrating same:
http://lightning.pwr.eng.osaka-u.ac.jp/lrg/temp/plane.html

The right side shows dissipation factor, when you are measuring capacitance, and Q when you are measuring inductance. While the unit doesn't perform the same functions as a Q meter, we are talking about 1/D in this case.

In the past, I've run into a problem that manifests itself as (2 X 2nd I.F.) rejection. Despite all forms of shielding around the filters, I just couldn't get rid of that 910kHz image. The cause turned out to be the 2nd LO at 10.245MHz feeding back into the 1st mixer. Enclosing this oscillator solved the problem. Since that time, I have switched to an NE602 for the 2nd mixer; the internal micropower oscillator in this device doesn't exhibit this problem.

I have been using the 10.240MHz crystals for a few years. Connecting the cold end of the crystal through a 4 to 40pF cap to ground allows you to warp it to 10.245MHz.

Many thanks for all the comments. I am curious. What about the W2IHY Technologies 8-Band Audio Equalizer and Noise Gate that is advertised in QST. Will it achieve similar results as a good speech processor?
